after reviewing the table sent to me if I am to understand it correctly, shows my seasonal residence to have an increase in my hydro rate of over 100%. That is unheard of, the entire south shore of Lake Kashwakamak I believe is on the same transmission line. This line also feeds many other customers I'm sure. What specifically defines low density? Transmission lines were built to develop and increase the tax base in this region when purchases of crown land were opened up many years ago. The economics of feeding properties must be much more efficient now then 60 years ago as the numbers of residences have greatly increased. Our line has been there since 1958, mind you in the wrong place, right over our property, that should never have happened. Maybe you should move it for our safety. My taxes in this area are higher at the residence in question then at my home in southern Ontario, and the services provided at the seasonal property are less.
