

October 31, 2023

**VIA RESS AND EMAIL**

Nancy Marconi  
Registrar  
Ontario Energy Board  
2300 Yonge Street, 27<sup>th</sup> Floor  
Toronto, ON M4P 1E4

Dear Nancy Marconi:

**Re: Enbridge Gas Inc. (Enbridge Gas, or the Company)**  
**EB-2020-0091 – Enbridge Gas Asset Management Plan Addendum - 2024**

As promised in the Integrated Resource Planning (IRP) Framework proceeding, Enbridge Gas will file an Asset Management Plan (AMP) or an Addendum to the AMP annually. The AMP describes system needs and constraints up to 10-years in the futures and will be filed every two years, while the Addendum provides updates to forecasts for the year in which it is filed and the following year. Each document also provides the status of consideration of IRP alternatives in regards to meeting these system needs.

During the deferred rebasing term, the AMP or an Addendum to the AMP has been filed in the annual rate applications to support the request for Incremental Capital Module (ICM). In 2022, EGI filed an AMP in the 2024 Rebasing application identifying the 10-year system needs for 2023 - 2032 (2023 – 2032 AMP). The 2023 – 2032 AMP is included as Appendix C in this filing.

For 2023, Enbridge Gas is filing an Addendum to the AMP as a stand-alone document with a cover letter as there is no ICM request for 2024 Rates. The Addendum provides an update to the capital budget for 2023 and 2024 set out in the 2023 – 2032 AMP. This Addendum should be reviewed in conjunction with the 2023 – 2032 AMP. Any changes beyond 2024 will be addressed in Enbridge Gas's 's 2025 – 2034 AMP which will be filed in Q4 2024.

Similar to prior years, the Addendum to the AMP is being filed for information purposes and Enbridge Gas is not seeking any approvals in relation to this filing.

October 31, 2023

# 1 Overview

Enbridge Gas Inc. (Enbridge Gas, EGI or the Company) filed an Asset Management Plan for the period of 2023 – 2032 (2023 – 2032 AMP) as part of Phase 1 of EGI's 2024 Rebasing Application<sup>1</sup>. This addendum provides an update to the Capital Budget for 2023 and 2024 set out in the 2023 – 2032 AMP. This addendum is not a standalone document and should be reviewed in conjunction with the 2023 – 2032 AMP. Given the dynamic nature of the ongoing identification of risks and opportunities as well as the execution of projects, this addendum only addresses changes impacting the current year (2023) and 2024 Budget year forecast. Any changes beyond 2024 will be addressed in EGI's 2025 – 2034 AMP (to be filed in Q4 2024) and reflect the outcomes from EB-2022-022 Phase 1 OEB Decision as appropriate.

EGI's 2025 – 2034 AMP will:

- Outline the proposed core Capital Plan for EGI from 2025 to 2034; and
- Identify Integrated Resource Planning (IRP) opportunities to meet system needs out to 2034.

Since the 2023 – 2032 AMP was filed in October 2022, there have emerged changes in investment needs and new developments for existing projects. EGI has reviewed these changes to understand their impact on the Capital Plan for 2023 and 2024. As described in Sections 2 and 3 below, the process for updating the 2023 and 2024 capital budgets involved the identification of changes/updates on an exception basis relative to the Capital Plan that was included in the 2023 – 2032 AMP. Updates are consistent with and reflect the updated 2023 and 2024 capital budgets as set out in EGI's July 6, 2023, Capital Update filing in *EB-2022-0200*<sup>2</sup>. The overall principles and asset lifecycle strategies outlined in the 2023 – 2032 AMP have not changed.

The updated 2024 Capital Budget is presented by asset class in **Table 1.0-1** below:

**Table 1.0-1: Summary of 2024 Capital Spend - Total EGI (Includes Overheads)**

| 2024 Capital Budget                          | Total EGI*                 |
|--|----------------------------|
| Growth                                       | 387.4                      |
| Distribution Pipe                            | 357.1                      |
| Distribution Stations                        | 83.5                       |
| Utilization                                  | 152.1                      |
| Compression Stations                         | 37.9                       |
| Liquefied Natural Gas                        | 8.3                        |
| Transmission Pipe & Underground Storage      | 264.1                      |
| Fleet & Equipment                            | 31.5                       |
| Real Estate & Workplace Services             | 63.0                       |
| Technology & Information Systems             | 102.4                      |
| Extended Alliance (EA) Fixed Overheads (O/H) | 39.8                       |
| <b>TOTAL</b>                                 | <b>1,527.1<sup>3</sup></b> |

\*Costs are expressed in millions of Canadian dollars.

<sup>1</sup> EB-2022-0200, Exhibit 2, Tab 6, Schedule 2

<sup>2</sup> EB-2022-0200, Exhibit 2, Tab 5, Schedule 3

<sup>3</sup> The 2024 Capital Budget is consistent with EB-2022-0200, Exhibit 2, Tab 5, Schedule 3 and includes PREP and Energy Transition adjustments per **Section 5.2**. The number excludes Community Expansion and CNG/RNG.

In this addendum, the following variances are shown by asset class:

- **Table 6.0-1:** updated 2024 Capital Budget versus the 2024 Capital Plan previously filed in the 2023 – 2032 AMP,
- **Table 6.0-2:** updated 2024 Capital Budget versus the 2023 Capital Budget previously filed in the 2023 – 2032 AMP, and
- **Table 6.0-3:** updated 2023 Capital Budget versus the 2023 9+3 Forecast previously filed in the 2023 – 2032 AMP

This addendum is representative of the best available information as of **September 2023**.

## 2 Monthly Forecast Process

As part of the process to review and prepare its Monthly Forecast, EGI used the capital specified in the given year's Workplan as a starting point. The Workplan gets finalized and approved at the beginning of each year and confirms which investments will be executed. This process aligns with the AIPM<sup>4</sup> process.

Each month, EGI undertakes a capital forecasting exercise where the Asset Managers for each asset class identify changes to the capital requirements, considering factors such as emerging needs, changing circumstances, potential for investment deferral, acceleration or re-pacing of investments, and project execution risks. All requests for emerging or revised projects must be supported with clear information regarding the purpose, need, and timing of the updated projects. A thorough review is performed to understand relevant project uncertainties and ensure that as much risk and opportunity are addressed as possible in the Monthly Forecast within the applicable capital constraint.<sup>5</sup>

More specifically, the approval process for the 2023 Workplan included the following steps:

1. Sign-off by Asset Management on investments submitted
2. Review by Asset Management, Finance, and subject matter advisors (to confirm portfolios for 2023)
3. Review by affected Directors
4. Review by Asset Management Steering Committee
5. Review and sign-off by the Vice President of Engineering and Integrity

---

<sup>4</sup> Appendix C, 2023 – 2032 AMP, Section 4.3 Asset Investment Planning and Management (AIPM) Process

<sup>5</sup> For 2023, the applicable capital constraint was established based on the 2023 capital forecast that was provided in the capital update in the 2024 rebasing application (EB-2022-0200, Exhibit 2, Tab 5, Schedule 4, Table 7).

### 3 Budget Refresh Process for 2024

As part of the process to review and refresh its 2024 Budget, EGI used the 2024 Capital Forecast included in the 2023 – 2032 AMP as a starting point and identified/made updates on an exception basis. The process aligns with the annual AIPM<sup>6</sup> process used to manage the budget throughout the year.

Asset Managers for each asset class identified changes to the capital requirements considering factors such as emerging needs, changing circumstances, potential for deferral, acceleration or re-pacing of investments, and project execution risks. All requests for emerging or revised projects must be supported with clear information regarding the purpose, need, and timing of the updated projects. A thorough review is performed to understand relevant project uncertainties and ensure that as much risk and opportunity are addressed as possible in the 2024 Budget within the applicable capital constraint.<sup>7</sup>

More specifically, the approval process for the 2024 Budget included the following steps:

1. Sign-off by Asset Management on investments submitted
2. Review by Asset Management, Finance, and subject matter advisors (to confirm portfolios for 2024)
3. Review by affected Directors
4. Review by Asset Management Steering Committee
5. Review and sign-off by the Vice President of Engineering & Integrity
6. Approval of 2024 Budget by EGI President
7. Approval of 2024 Budget by Enbridge Inc. Board of Directors

---

<sup>6</sup> Appendix C, 2023 – 2032 AMP, Section 4.3 Asset Investment Planning and Management (AIPM) Process

<sup>7</sup> For 2024, the applicable capital constraint was established based on the 2024 forecast provided in the capital update in the 2024 rebasing application (EB-2022-0200, Exhibit 2, Tab 5, Schedule 4, Table 8).

# 4 Strategic Priorities Updates

Enbridge's 2023 Enterprise Strategic Priorities (see **Figure 4.0-1**) are defined to enable the organization to achieve its vision to be the leading energy delivery company in North America. Asset Management actions and decisions align with these strategic priorities, contribute to EGI's success, and support the Company's purpose of fueling people's quality of life, while maintaining the foundation of the business, supporting the energy transition, and positioning the Company for future growth.

## Our strategic priorities

**Safety and  
Operational Reliability**

**Extend  
Growth**

**Maintain Strong  
Balance Sheet**

**Disciplined  
Capital Allocation**

**Lead in Energy  
Transition**

**Figure 4.0-1: Enbridge's 2023 Enterprise Strategic Priorities**

# 5 Asset Management Developments for 2024

## 5.1 IRP Asset Management Plan Evaluation Update

In 2021, the OEB released its Decision and Order on EGI's IRP proposal<sup>8</sup>, indicating that EGI's AMP should include the status of consideration of IRP plans in meeting system needs, the result of binary screening, and details on the evaluation. EGI continues to evaluate investments within the AMP for IRP implementation potential to eliminate, reduce, or defer the project scope based on the technical and economic feasibility. **Appendix B – IRP (Updated)** reflects the current state of this IRP evaluation process.

Investments that have passed the binary screening stage can be categorized as growth or non-growth investments. EGI uses this categorization, along with the investment's in-service date and forecasted costs to prioritize the Company's IRP evaluations. The rationale behind this categorization and prioritization is that EGI has found, via its technical evaluations, that the implementation of an IRP alternative (IRPA) is more likely to impact the scope of growth-driven investments, given that non-growth investments are driven by the need to maintain the integrity and reliability of existing system assets to serve customers on the network.

Since the filing of the 2023 – 2032 AMP, 1194 investments have been added to the 2023 to 2032 forecast (to be referred to as "new investments to Appendix B"), which were not included in the original Appendix B. A large portion of these new investments to Appendix B are related to carryover project costs from prior year investments and other smaller, quick-response investments that are funded through blanket accounts, e.g. emergent safety issues. The attached **Appendix B – IRP (Updated)** includes investments from the 2023 – 2032 AMP as well as the new investments to Appendix B. Each investment in the **Appendix B – IRP (Updated)** has been binary screened.

Within the rebasing proceeding, EGI indicated that it would complete the technical evaluations for the investments within the 2023 – 2032 AMP by Q3, 2023; however, with the addition of the new investments to Appendix B, EGI has decided to continue to prioritize completing IRP evaluations for all growth driven investments in Appendix B, as opposed to completing IRP evaluations for all investments from the original 2023 – 2032 AMP filed in 2022. This ensures that EGI remains focused on those investments with a higher likelihood of being impacted by an IRPA.

- EGI is targeting to complete the technical evaluations of both the remaining and new investments to Appendix B that are growth driven by the end of 2023. The results will be reflected in the 2023 IRP Annual Report.
- All remaining non-growth investments, except for the Enhanced Distribution Integrity Management (EDIMP)<sup>9</sup> related investments and other select investments, will have their IRP technical evaluation deferred to the following year. EGI is targeting to complete the technical evaluations for both the remaining and new pipeline investments from the 2023 – 2032 AMP and results to be reflected 2025 – 2034 AMP. EGI is also looking to assess if any of these investments could be grouped and targeted with a regional IRPA Plan.

The following list highlights the IRP evaluation progress of the 3087 investments in the 2023 – 2032 AMP:

- 809 (26.2%) were deemed not subject to any IRP process because they related to non-gas-carrying investments.
- 1392 (45.1%) were screened out using binary screening.
- 632 (20.4%), at the time of filing this addendum, had undergone a completed technical evaluation, and 63 had passed the evaluation.
- 254 (8.2%) remain to undergo technical evaluation or have the evaluation currently in progress as of the time of filing.

---

<sup>8</sup> EB-2020-0091

<sup>9</sup> See Section 5.3 below and EB-2022-0200, Decision on Settlement Proposal, Exhibit O1, Tab 1, Schedule 1, pp. 30-31, August 17, 2023, where parties agreed to the establishment of a DIMP Variance Account that will track EGI's spending on the DIMP and EDIMP programs.

- 43 investments under the Asset Class of Growth are in the queue to have their technical evaluations completed by the end 2023.
- 5 investments under the Asset Class of Transmission Pipe & Underground Storage will have the options assessed prior to the Leave to Construct (LTC) application.
- 197 investments under the Asset Class of Distribution Pipe have an IRP evaluation status of "On Hold"<sup>10</sup>. These investments will be re-evaluated annually for project scope and timing updates to allow for appropriate resource allocation for the IRP evaluation process.
- 9 investments in the EDIMP have a technical evaluation status of "In Progress" and are awaiting further integrity assessment to confirm project scope and timing. Preliminary technical evaluations have been conducted based on the current scope of the investments in 2023 – 2032 AMP. Technical evaluations will be updated to include the scope impacts of the Asset Management portfolio from the EDIMP integrity assessment.
- Investments that have passed the technical evaluation will proceed to the economic evaluation stage. No economic evaluations have been completed at the time of filing this addendum.

The following list highlights the IRP evaluation progress of the 1194 new investments to Appendix B:

- 140 (11.7%) were deemed not subject to any IRP process because they related to non-gas-carrying investments.
- 904 (75.7%) were screened out using binary screening.
- 66 (5.5%), at the time of filing this addendum, had undergone a completed technical evaluation, and none had passed the evaluation.
- 84 (7.0%) remain to undergo technical evaluation or are being technically evaluated as of the time of filing this addendum.
- 24 investments under the Asset Class of Growth are in the queue to have their technical evaluations completed by the end of 2023.
- 60 investments under the Asset Class of Distribution Pipe and Distribution Station have an IRP evaluation status of "On Hold". These investments will be re-evaluated annually for project scope and timing updates to allow for appropriate resource allocation for the IRP evaluation process.

## 5.2 Energy Transition

EGI has incorporated Energy Transition<sup>11</sup> impacts to the Customer Connections forecast and ensured appropriate adjustments have been reflected in the Growth and Utilization asset classes, including Customer Connections portfolios under Growth, in the updated 2024 Budget under **Table 6.0-1**. These impacts are in alignment with undertaking response *EB-2022-0200, Exhibit J14.2*, and lower Gas Infrastructure - Growth & Customer Connections investment by \$2.0M in 2024 due to the reduction in customer attachments by 322<sup>12</sup> after Energy Transition assumptions are incorporated. Note that Energy Transition assumptions had previously been incorporated into the Distribution System Reinforcement forecast under Growth in the 2023 – 2032 AMP and in the Capital Update<sup>13</sup> filed in Phase 1 of the rebasing application.

EGI has committed to evolving its Energy Transition plan, including conducting a regional Energy Transition analysis with stakeholder engagement, which the Company proposes to file with the next rebasing application.<sup>14</sup> In the interim, EGI will continue to evolve its demand forecasting process, including to review and, where required, update the Energy Transition assumptions used in the forecasts of customer additions, design hour, and design day. EGI intends that future IRP

<sup>10</sup> On hold due to project timing/scoping to be confirmed.

<sup>11</sup> EB-2022-0200, Exhibit 1, Tab 10, Schedule 4

<sup>12</sup> EB-2022-0200, Exhibit I.2.6-ED-94, Table 2

<sup>13</sup> EB-2022-0200, Exhibit 2, Tab 5, Schedule 4

<sup>14</sup> EB-2022-0200, Reply Argument, paragraph 78, filed October 11, 2023

assessments included with a LTC, or IRP plan filed with the OEB will incorporate the assessment of demand forecast sensitivities to consider Energy Transition related uncertainties.<sup>15</sup> In its Reply Argument in EB-2022-0200, EGI has proposed updated customer attachment policies to be in effect as of January 1, 2025. The implications of these changes will be reflected in the 2025 – 2034 AMP.

## 5.3 Integrity Management Program Enhancements

EGI continues to evolve its Integrity Management Program based on industry best practices and incident learnings. EGI has developed a quantitative risk model to assess the risk for pipeline assets within the distribution system that identifies and prioritizes assets approaching the end of life that need replacing. Ninety-nine percent of the transmission pipeline assets are already assessed using the quantitative risk model with the balance to be incorporated by the end of 2023. Improvements have been made to the transmission risk model to include additional hazards, consequences, and the application of Safety Targets, to align with EGI's risk evaluation criteria.

In addition, EGI recently introduced an EDIMP which is a targeted program to manage the Integrity threats of higher-priority distribution pipelines, by improving the understanding of the condition, fitness for service, and risks associated with the operation of those assets.

## 5.4 Growth Strategy Developments

### 5.4.1 Panhandle Regional Expansion Project

The Panhandle Regional Expansion Project (PREP)<sup>16</sup> is required to provide a reliable, secure, economical natural gas supply to meet the growing design day demand of the EGI Panhandle Transmission System which serves in-franchise markets (including residential, commercial, and industrial customers). The project need was originally determined based on nonbinding Expression of Interest (EOI) conducted in February 2021 followed by a binding Reverse Open Season (ROS) in October 2021.

On June 10, 2022, EGI applied to the OEB under docket *EB-2022-0157* for LTC the following facilities, which were also reflected in EGI's 2023 – 2032 AMP and Capital Forecast filed in *EB-2022-0200 Exhibit 2, Tab 6, Schedule 2*:

- Approximately 19 km of Nominal Pipe Size (NPS) 36 natural gas pipeline with a Maximum Operating Pressure (MOP) of 6,040 kPag from the existing Enbridge Gas Dover Transmission Station in the Municipality of Chatham-Kent to a new valve site in the Municipality of Lakeshore (Panhandle Loop); and,
- Approximately 12 km of NPS 16 natural gas pipeline with a MOP of 6,040 kPag in the Municipality of Lakeshore, the Town of Kingsville, and the Municipality of Leamington (Leamington Interconnect).

On February 1, 2023, EGI filed a letter stating that, following the receipt of new cost information, the Company also reassessed the capacity position of the Panhandle System based on actual 2022 attachments and their system locations, as well as updated 2023 customer demand. As a result, the Company anticipated that incremental demand for Winter 2023/2024 could be accommodated and that the project's in-service date could be deferred one year from November 1, 2023, to November 1, 2024. Based on this, EGI asked the OEB to continue holding the application in abeyance until no later than August 2023. On February 23, 2023, EGI launched a second nonbinding EOI and concurrent binding ROS for the Panhandle Market. As a result of the EOI and ROS, the original project in-service date was deferred one year, from November 1, 2023, to November 1, 2024. In addition, EGI also adjusted the project's proposed scope by removing the Leamington Interconnect.

On June 16, 2023, EGI filed its amended LTC application for PREP based on the following scope of proposed facilities:

- No change in scope to the Panhandle Loop (i.e., 19 km of NPS 36 natural gas pipeline), with an updated estimated in-service date of November 1, 2024 (previously November 1, 2023). The Leamington Interconnect has been removed from the application.

<sup>15</sup> EB-2022-0200, Reply Argument, paragraph 128, filed October 11, 2023

<sup>16</sup> EB-2022-0157

- PREP also includes ancillary measurement, pressure regulation, and station facilities within the Township of Dawn Euphemia and in the Municipality of Chatham-Kent.

Construction of PREP to meet the needs of customers in the Panhandle Market will be contingent upon the OEB's grant of leave-of-construct in *EB-2022-0157* as well as approval of EGI's proposed levelized cost treatment for PREP in *EB-2022-0200*.

Further details about PREP are available within the filed evidence in *EB-2022-0157* and **Table 6.0-1** and **Table 6.0-3**.

## 5.4.2 Kingston Reinforcement Project

The East Kingston Creekford Rd Reinforcement project was a planned \$24.3 million capital reinforcement for 2024. As originally reflected in the 2023 – 2032 AMP, the proposed facility project was a replacement of the entire existing NPS 6 pipeline from Westbrook check measurement station (CMS) to the Woodbine town border station (TBS) to account for forecasted growth and to address class location and depth of cover issues which exist on the current Kingston Lateral.<sup>17</sup> The growth in the Kingston area is driven by general service growth. As described below, Enbridge Gas has implemented two IRPAs to defer this project. Deferring this project provides additional time to assess and determine if a pipeline replacement project is needed, or if Ontario's energy transition will impact growth in a way, and in time, to avoid additional infrastructure.<sup>18</sup>

The project was a 6.2 km NPS 8, 6,895 kPa relocation project off the lateral feeding the City of Kingston, Ontario, with a project in-service date of 2024. The drivers of this project included growth and system integrity issues. EGI reviewed this project for IRPAs including:

- Supply-side alternatives: Incremental pressure from TC Energy and Compressed Natural Gas (CNG).
- Demand-side alternatives: Enhanced Targeted Energy Efficiency (ETEE), and a Contract & Interruptible Rates review.

The Company implemented a CNG option that supported the system in peak demand conditions for winters of 2022/2023 and 2023/2024. The CNG alternative will be reviewed in 2024 to determine if this solution is still required for the winter of 2024/2025. EGI implemented an in-franchise binding ROS which offered contract customers within the proposed project service area an opportunity to turn back or reduce their existing contracted capacity. One response was received from a contract customer to reduce their firm contracted capacity, thereby reducing the total peak demand on the system. For further details on this IRPA, please refer to the 2022 Non-Commodity Deferral Disposition application, *EB-2023-0092, Exhibit H*.

As mentioned above, in addition to addressing the increased forecasted demands, the proposed facility project would also address the depth of cover and class location issues on the current Kingston lateral. The depth of cover has been identified as a "medium risk" issue and has since been deemed acceptable for continued monitoring and assessment of the exposed location. Changes in depth of cover are event-based. As such, any timelines for remediation will be based on findings from monitoring programs. The class location compliance issues can also be monitored, but not indefinitely; however, a delay to 2027 appears reasonable, and the monitoring during this period will identify if action is required sooner. The proposed IRPAs are not able to address the class location and depth of cover concerns; therefore, Enbridge Gas will continue to monitor these assets to ensure the risk remains tolerable. As the project is reassessed to identify when future system reinforcement may be required, remedies to the class location and depth of cover concerns will be considered.

<sup>17</sup> EB-2020-0091, OEB Decision and Order, p. 80

<sup>18</sup> EB-2023-0092, Exhibit C, Tab 1

## 5.5 Distribution Pipe Strategy Developments

### 5.5.1 St. Laurent Pipeline Replacement Project

The St. Laurent Pipeline Replacement Project (SLPRP) involves a critical pipeline that directly or indirectly serves natural gas to approximately 165,000 residential, commercial, industrial, and institutional customers in the City of Ottawa and Gatineau, Quebec. The pipeline traverses a highly urban location and is near residential, commercial and office buildings, as well as high-traffic motorways such as the 417 Highway and the St. Laurent Boulevard.

Following the 2022 OEB decision to reject the LTC application<sup>19</sup>, Enbridge Gas reassessed the reliability of the St. Laurent Pipeline by gathering additional condition information. Approximately 39% of the St. Laurent pipeline system was inspected using an in-line inspection (ILI) crawler tool. Several key observations informed the reliability assessment:

- Presence of significant corrosion: several corrosion features were of significant depth (>50% depth), including one with reported depth of 80% or greater (ILI tool is unable to size defects greater than 80% depth of the Nominal Wall Thickness (NWT)). The feature was considered to require immediate repair to ensure safety and reliable service and was subsequently urgently replaced in November 2022. There is a significant possibility that additional severe corrosion features exist on the uninspected segments of the line.
- Degraded ILI tool performance: The tool's performance was degraded as compared to the vendor's stated specifications for sizing and detection. This included an apparent under call bias (i.e., actual defect dimensions were more severe than reported in the ILI).
- High number of suspected third-party damage features: 386 dents were identified over the 4.5 kms of inspected length.

A risk assessment was performed to evaluate the risk related to the continued operation of the pipeline in its current state. Using the data gathered, a Quantitative Risk Assessment (QRA) has been completed to assess the residual risk of the St. Laurent Pipeline system. The QRA uses industry standard reliability methods and published failure rates to form a comprehensive in-depth assessment of potential threats that could affect the pipeline. The reliability of the pipeline was compared against industry failure rate thresholds and significant incident benchmarks. Additionally, the QRA was supplemented with consequences of various outcomes and mapped to the Enbridge Standard Operational Risk Assessment Matrix.

Based on the assessment and evaluation criteria, Enbridge Gas concluded that:

- 8.8 km of the 11.2 km pipeline (79%) fails the CSA Z662 - Annex O reliability thresholds. Several segments fail the reliability thresholds by several orders of magnitude.
- The rate of estimated significant incidents on the St. Laurent Pipeline, is much higher than the historical average observed in the industry (e.g. PHMSA<sup>20</sup> Database).
- The pipeline risks plotted on the Enbridge Standard Operational Risk Matrix shows that many of the Financial, Operational Disruption, and Health & Safety Risk scenarios meet the Enbridge definition of "High Risk" or "Very High Risk."

Subject to the receipt of LTC, construction work is scheduled to begin in 2024 with \$75.7M being put into service in 2024, \$140.5M in 2025, and \$7.2M for restoration and final service work in 2026. A LTC application will be filed with the OEB in November 2023, which will detail the relevant analysis and findings, including IRP considerations and options assessment. The variance description accounting for forecast changes between the 2023 – 2032 AMP and this addendum (including changes related to the SLPRP) has been provided in **Table 6.0-2**.

## 5.6 Compression Station Developments

---

### 5.6.1 Dawn to Corunna

The Dawn to Corunna Replacement Project involves the construction of approximately 20 km of NPS 36 natural gas pipeline between the Corunna Compressor Station (CCS) and the Dawn Operations Centre, as well as associated station work. The CCS and the Dawn Operations Centre are the two main compression locations of the Dawn Hub. The project enables the retirement of 7 compressor units at the CCS to address known obsolescence, reliability, and safety risks and maintain equivalent withdrawal, injection and working capacity of the Dawn Hub.

The current cost forecast for this project is approximately \$376M and is a refined forecast using contactor Request for Proposal (RFP) estimates, detailed engineering design, and actual costs from current construction activities. The current cost forecast represents an approximately \$125M increase from the original cost estimate as filed in EB-2022-0086 (\$251M), which was derived using preliminary design stage information and Request for Information (RFI) quotes from contractors.

# 6 Summary of Capital Expenditures

**Table 6.0-1** compares the 2024 Capital Plan that was included in the 2023 – 2032 AMP versus the updated 2024 Capital Budget and highlights the key drivers for notable variances. As discussed in **Section 3**, emerging and revised projects were identified and evaluated based on the existing 2024 portfolio. No changes have been reflected in the 2025 portfolio and beyond, and, as such, no updates were required to the assumptions in Section 6.4 of the 2023 – 2032 EGI AMP. No changes were made to inflation assumptions for future year projects. Updated cost estimates were prepared for new or revised 2024 projects. Projects with solution scopes still under development are not included in the 10-year portfolio of spend.

**Table 6.0-1: 2024 EGI Capital Budget and Variance Explanations (Includes Overheads)**

| Asset Class       | 2024 AMP | 2024 Budget | Variance | Variance Explanation  |
|-------------------|----------|-------------|----------|---|
| Growth            | 354.3    | 387.4       | 33.1     | <p><b>Customer Connections:</b> An increase of \$53.1M is required for customer connections and is related to an increase in new connections compounded with inflationary pressures in construction and material costs.</p> <p><b>Growth:</b> A decrease of \$19.8M is primarily due to the deferral of \$24.1M for the East Kingston Creekford Road Reinforcement<sup>21</sup> through an interim solution using CNG to support system peak demands, cancellation of \$19.9M for the Wheatley 1B Panhandle Distribution Reinforcement due to change in forecasted customer demands, and deferral of several smaller growth reinforcement projects. These reductions are partially offset by \$15.2M in forecasted carryover costs from 2023, and \$9.3M of new reinforcement projects identified following review of specific customer connection projects and resultant system constraints.</p>   |
| Distribution Pipe | 368.3    | 357.1       | (11.2)   | <p>The variance of \$11.2M is primarily attributed to the deferral of \$36.1M for the Wilson Avenue project and \$18.5M for the Port Stanley replacement project so that further inspections and health assessments can be made as part of the EDIMP before finalizing the need and scope for these projects. Also deferred were \$4.7M costs associated with integrity depth of cover mitigation and \$9.2M costs for integrity initiative and geohazard mitigation. This is partially offset by a \$48.1M increase in integrity digs, which is primarily a result of an increase to the expected number of digs compounded by inflationary pressures, a \$0.5M increase in integrity retrofits, a \$3.8M increase in other pipe main replacement, relocation &amp; service relay, \$2.5M in carryover costs from 2023 to 2024, and an \$8.7M increase in corrosion costs identified through inspections and surveys (for new mains &amp; bridge crossing replacement projects).</p> |

<sup>21</sup> EB-2020-0091, OEB Decision and Order, p. 80

| Asset Class  | 2024 AMP | 2024 Budget | Variance | Variance Explanation   |
|--|----------|-------------|----------|--|
| <b>Distribution Stations</b>                       | 120.6    | 83.5        | (37.1)   | The decrease of \$37.1M is attributable to \$80.5M in deferral of smaller station projects during portfolio reprioritization. This is partially offset by \$8.1M in forecasted carryover costs from 2023 into 2024, \$5.6M in new station projects having been identified through inspections, and \$29.7M in cost increases on smaller station projects relating to increasing construction and material costs compared to the original estimates.  |
| <b>Utilization</b>                                 | 146.5    | 152.1       | 5.6      | The increase of \$5.6M is primarily a result of an increase in meter orders to ensure sufficient inventory for the increase in forecasted customer connections and meter exchanges.  |
| <b>Compression Stations</b>                        | 38.6     | 37.9        | 0.7      | The increase of \$0.7M is predominantly attributable to work expected to carry forward for 2023 from the Dawn to Corunna <sup>22</sup> project in addition to \$2.1M of smaller projects with forecasted carryover costs, \$8.5M in new projects identified through inspection activities and failures, and approximately \$5.9M in projects where cost estimates have increased through project development from 2023 and prior years into 2024 which have added new cost pressures. These have been offset by approximately \$24.7M in project cancellations and deferrals, the most significant of which is the deferral of \$16M for the Dawn C Compression Life Cycle project to allow time for completion of the reliability assessment to inform the updated scope. |
| <b>Liquefied Natural Gas</b>                       | 0.3      | 8.3         | 8.0      | The increase of \$8M for LNG relates mainly to an unplanned \$7.6M required for an unplanned foundation replacement and overhaul of a compressor at the Hagar LNG Plant and \$0.4M in Multi-Sector Air Pollutants Regulations (MSAPR) compliance mitigations which were deferred from 2023 as part of portfolio reprioritization.  |
| <b>Transmission Pipe &amp; Underground Storage</b> | 171.7    | 264.1       | 92.4     | The increase of \$92.4M is primarily a result of \$189.3M of the deferral and increase in the forecast for Panhandle Regional Expansion Project (PREP) <sup>23</sup> into 2024. This is partially offset by decreases from the deferral of \$23.1M for the Dawn to Parkway Expansion Project: Kirkwall to Hamilton Loop, \$50.5M for the Leamington Interconnect Project, \$7.7M for the Waubuno replacement wells, and delayed expenditures amounting to \$29.7M for the Panhandle Line Replacement. Additional increases include \$4.4M associated with filter replacements, \$10.3M   |

<sup>22</sup> EB-2022-0086

<sup>23</sup> EB-2022-0200

| Asset Class                                 | 2024 AMP       | 2024 Budget    | Variance    | Variance Explanation  |
|---|----------------|----------------|-------------|---|
|   |                |                |             | increase to integrity management primarily driven by an increase to expected number of digs compounded by inflationary pressures, and other smaller project increases determined through cost refinement.   |
| <b>Fleet &amp; Equipment</b>                | 35.0           | 31.5           | (3.5)       | The decrease of \$3.5M is related to \$2.2M in anticipated carryover costs and new equipment and tool investments offset by reductions during reprioritization for vehicles and equipment purchases.  |
| <b>Real Estate &amp; Workplace Services</b> | 56.6           | 63.0           | 6.4         | The increase of \$6.4M is primarily related to \$14.1M of cost increase for Station B attributable to inflationary pressures and execution timing, \$13.3M of deferred cost and inflationary pressures associated with the Ottawa building construction, and \$3.7M in smaller project increases, \$8.8M of project costs planned for prior years carrying into 2024 due to shifts in construction pacing and addition of several other smaller projects, with these increases offset by a \$25.2M deferral of the Kennedy Road new building construction, and \$9.4M worth of several other small reductions and deferrals relating to reprioritization of projects and forecast refinements.  |
| <b>Technology &amp; Information Systems</b> | 112.4          | 102.4          | (10.0)      | The decrease of \$10.0M is related to reprioritization of the TIS Business Solutions portfolio based on business needs leading to \$11.6M in reductions and \$13.9M in deferrals offset by \$14.7M in new investments added to the forecast and some minor carryover costs.   |
| <b>EA Fixed O/H</b>                         | 21.9           | 39.8           | 17.9        | The increase of \$17.9M is related to renegotiation of the Extended Alliance Contracts. EGI recently completed a competitive bid process for construction services to test the competitive market. This provided the opportunity to review the total cost structure of their service model and propose new contract terms for the future five years. Previous contracts have mitigated inflationary impacts. However, the current market conditions have driven higher inflationary increases to fixed overheads which include labour rates, fuel costs, facility, and maintenance costs. Select contracts had a provision for limited inflationary adjustment that was below market inflation. Other impacts to fixed overheads include but are not limited to business-to-business systems alignment, harmonization of policies and procedures, changing service providers in two regions (Northeast and GTA East), and increased capital investment costs. Additionally, the cost structure proposed in the new contract realigned the allocation of unit rates and fixed overhead which resulted in an overall construction cost below inflation. |
| <b>Total</b>                                | <b>1,426.1</b> | <b>1,527.1</b> | <b>95.4</b> |   |

Table 6.0-2 shows the 2023 9+3 Forecast compared to the 2024 Capital Budget for EGI.

**Table 6.0-2: 2023 9+3 Forecast vs 2024 EGI Capital Budget and Variance Explanations (Includes Overheads)**

| Asset Class                  | 2023 9+3 Forecast | 2024 Budget | Variance | Variance Explanation   |
|------------------------------|-------------------|-------------|----------|--|
| <b>Growth</b>                | 377.9             | 387.4       | 9.5      | <p><b>Customer Connections:</b> A decrease of \$24.9M is forecasted for Customer Connections in 2024 due to the decreased estimated customer growth forecast in 2024, as well as the increased number of actual customers being added in 2023 which has driven the forecast higher in 2023.</p> <p><b>Growth:</b> An increase of \$34.4M is primarily due to an increase in reinforcement projects including the HAMI: Caledonia Transmission Station Rebuild and the NW 2013 Dundalk XHP Reinforcement SRP. Other drivers include development spend to support the Hamilton Industrial Reinforcement Project , and the Enbridge Gas Distribution System Hydrogen Feasibility Study. All Reinforcement projects are subject to the IRP Assessment Process. For additional details, refer to Appendix B.</p>            |
| <b>Distribution Pipe</b>     | 257.5             | 357.1       | 99.6     | <p>The increase of \$99.6M in 2024 is primarily related to inclusion of \$69.0M to start construction of St. Laurent Pipeline Replacement Project<sup>24</sup>, an increase of \$21.0M for Integrity due to an increased forecast number of digs partially offset with a reduction in retrofits, an increase of \$6.8M of Service Relays to address deferred 2023 AMP fittings, an increase of \$7.2M for additional municipal relocation work, an increase of \$15M to address deferred 2023 corrosion work, with smaller increases and decreases in Main Replacement work netting an additional \$13.9M increase in 2024. These increases are partially offset by reductions of \$20.8M and \$12.5M for the Kipling Oshawa Loop (KOL) Lakeshore Cherry to Bathurst and Parliament Street projects, respectively.</p> |
| <b>Distribution Stations</b> | 63.4              | 83.5        | 20.1     | <p>The increase of \$20.1M is primarily related to a \$6.9M increase in Facilities Integrity Management Program assessments from prior year deferrals driven by portfolio reprioritization, a \$10.5M increase in smaller station rebuilds, and \$2.7M in smaller increases to Gate, Feeder and A Station projects, Inside Regulator Room, and CNG projects driven by portfolio reprioritization in 2023.</p>  |
| <b>Utilization</b>           | 168.0             | 152.1       | (15.9)   | <p>The decrease of \$15.9M in 2024 is primarily due to reductions in the Reg Refit program of \$9.3M as a result of adjustments in the forecasted number of meter exchanges, as well as reductions in overall Meter Orders by \$4.5M driven by the</p>   |

<sup>24</sup> EB-2020-0293

| Asset Class  | 2023 9+3 Forecast | 2024 Budget | Variance | Variance Explanation   |
|--|-------------------|-------------|----------|--|
|  |                   |             |          | adjustments made to both the meter exchange program and reductions seen in the Growth portfolio. There is also an overall reduction of \$2.1M for Monitoring Systems due to reprioritization of requirements for this program.   |
| <b>Compression Stations</b>                        | 349.6             | 37.9        | (311.7)  | The decrease of \$311.7 is primarily related to the completion of several larger projects in 2023. These include the Dawn to Corunna Replacement <sup>25</sup> and Dawn to Corunna (Dawn Tie-In) projects in 2023 totaling a reduction of \$310.9M, replacement of a failed control valve including necessary piping upgrades totaling \$3.5M, replacement of a compressor foundation at Corunna Compressor Station for \$3.2M, \$1.7M associated with valve controller upgrades to comply with the federal methane emissions regulations, and \$7.0M in smaller projects. These reductions for 2024 are partially offset by \$5.7 M to replace leaking valves, \$2.2M in initial costs related to the Waubuno Compression Life Cycle project, \$1.4M in residual costs for the Parkway Plant C Power Turbine failure, and as well as \$5.3M in increases for several other smaller investments related to portfolio prioritization. |
| <b>Liquefied Natural Gas</b>                       | 2.0               | 8.3         | 6.3      | The variance of \$6.3M is related to the difference in 2023 pre-spend and 2024 execution costs for an unplanned compressor overhaul and foundation replacement at the Hagar LNG Plant.   |
| <b>Transmission Pipe &amp; Underground Storage</b> | 97.8              | 264.1       | 166.3    | The increase of \$166.2M is primarily due to \$138.1M of increased expenditures for PREP <sup>26</sup> , increase of \$10.1M in integrity forecast, \$6.1M increase in spend associated with the Crowland Wells Upgrade, wellhead upgrades and observation wells, \$8M in increases associated with filter replacements, A1 Wells replacements and Dow A McPlank Connection and finally \$2.5M for Class Location replacements. There is also a net increase of \$0.85M in Growth Projects primarily due to \$1.3M from Kirkwall to Hamilton Project. Additionally, there is a \$0.35M increase in multiple Lands/Structures investments such as atmospheric tanks replacement, platform installation and roadways & laneway improvement.  |
| <b>Fleet &amp; Equipment</b>                       | 8.8               | 31.5        | 22.7     | The increase of \$22.7M is primarily due to an increase in vehicle purchases to meet EGI's vehicle replacement strategy and in response to limited purchases in 2023 caused by a reprioritization of replacements in 2023.   |

|---|-------------------|----------------|-------------|---|
| <b>Real Estate &amp; Workplace Services</b> | 69.6              | 63.0           | (6.6)       | The decrease of \$6.6M is attributed to the spend on building projects including Ottawa, Station B and Dawn EOC MCR.  |
| <b>Technology &amp; Information Systems</b> | 44.4              | 102.4          | 58.1        | The increase of \$58.1M is driven primarily by projects that are required to support process and system enhancements while in parallel reducing EGI's operational and cybersecurity risks. Significant projects include: \$15.4M General Service Rebasing Changes, \$11.8M Contract Market Systems - Technology Obsolescence, an increase of \$9.5M for Infrastructure (Hardware Replacement, Desktop & Toughbook Replacement, GPS Hardware Lifecycle, Network Sustainment), \$5.1M Utility Weather & Demand Harmonization – Rebasing, \$5.1M 5-week Planning Tool, \$3.7M Contract Market Harmonization, \$2.4M Enterprise Contact Center, \$2.3M Enterprise Contact Center, \$2.1M AWS Phase 3, and \$0.7M increases or additions to TIS investments.   |
| <b>EA Fixed O/H</b>                         | 23.7              | 39.8           | 16.1        | The increase of \$16.1 million is related to renegotiation of the Extended Alliance Contracts. EGI recently completed a competitive bid process for construction services to test the competitive market. This provided the opportunity to review the total cost structure of their service model and propose new contract terms for the future five years. Previous contracts have mitigated inflationary impacts. However, the current market conditions have driven higher inflationary increases to fixed overheads which includes salary, fuel costs, facility, and maintenance costs. Select contracts had a provision for limited inflationary adjustment that was below market inflation. Other impacts to fixed overheads include but are not limited to business-to-business systems alignment, harmonization of policies and procedures, changing service providers in two regions (Northeast and GTA East), and increased capital investment costs. Additionally, the cost structure proposed in the new contract realigned the allocation of unit rates and fixed overhead which resulted in an overall construction cost below inflation. |
| <b>Total</b>                                | <b>1,462.1</b>    | <b>1,527.1</b> | <b>65.0</b> |   |

\*Costs are expressed in millions of Canadian dollars.

**Table 6.0-3** shows the 2023 Capital Budget published in the 2023 – 2032 AMP compared to the 2023 9+3 Forecast for EGI.

**Table 6.0-3: 2023 9+3 Forecast vs 2023 AMP Forecast and Variance Explanations (Includes Overheads)**

| Asset Class                  | 2023 AMP | 2023 9+3 Forecast | Variance | Variance Explanation   |
|------------------------------|----------|-------------------|----------|--|
| <b>Growth</b>                | 275.3    | 377.9             | 102.6    | <p><b>Customer Connections:</b> An increase in \$106.7M is related to an overall increase in forecasted new customer connections compounded with inflationary pressures in construction and material costs.</p> <p><b>Growth Reinforcement:</b> There have been \$40.9M in new growth projects and increases to existing projects due to inflationary pressures of material and construction cost identified in 2023. These have been offset by equivalent savings from deferrals and reprioritization of planned growth projects following review of specific customer connection projects and resultant system constraints. As a result of the funding and deferrals and reprioritization, there is an overall decrease of \$4.1M.</p>   |
| <b>Distribution Pipe</b>     | 261.9    | 257.5             | (4.4)    | <p>The variance of \$4.4M is driven by reductions resulting from work reprioritization, partially offset by various cost pressures in 2023. These cost pressures include a \$23.8M of 2022 carryover costs for the KOL Lakeshore Cherry to Bathurst replacement, a \$2.3M in AMP fitting works, a \$1.6M increase in class location works, a \$2.3M increase in material costs for the Marten River retrofit, a \$1M increase in construction costs for the Niagara ILI retrofit and a \$2.2M increase in integrity digs due to an increase in the number of digs. These cost pressures were partially offset by reprioritization-driven reductions of \$5.7M in anode replacement, \$16.8M in main replacement expenditures, and \$15.1M in relocation work caused by deferral of municipal works.</p>  |
| <b>Distribution Stations</b> | 149.3    | 63.4              | (85.9)   | <p>The decrease of \$85.9M can be attributed to three main portfolios:</p> <ul style="list-style-type: none"> <li>DS - Gate, Feeder &amp; A Stations - \$47.4M total due to \$23.6M reduction for the delay of the Crowland Station, \$9.4M due to deferral of the Parkway Gate Station, \$19.2M for the delay of the Lisgar Gate Station as the project is rescoped, and \$20.4M of other smaller station projects during portfolio reprioritization; which are partially offset by \$4.6M for the St. John's Feeder station delay and \$20.2M of other smaller projects.</li> <li>DS - Integrity Initiatives - \$5.8M reduction of the Facilities Integrity Management Program (FIMP) Station program deferral.</li> <li>DS - Station Rebuilds &amp; B and C Stations - \$28.2M total due to \$9.2M reduction for the deferral of the Brantford Gate Station, \$34M for the</li> </ul> |

| Asset Class                             | 2023 AMP | 2023 9+3 Forecast | Variance | Variance Explanation   |
|---|----------|-------------------|----------|--|
|   |          |                   |          | reduction of smaller station projects during portfolio reprioritization that are offset by \$15M in increases due to carry over costs from 2022 and other smaller investments.<br>The balance of reductions can be found in the DS – CNG and DS - Inside Regulator & External Regulatory Room Program portfolios.  |
| Utilization                             | 136.5    | 168.0             | 31.5     | The increase of \$31.5M primarily consists of \$5.3M for delayed meters ordered for 2022, an increase of \$19.2M for meters ordered to build inventory necessary to keep up with planned work, a \$6.8M increase in regulators and meter exchange labour costs associated with a moderate increase in planned work to catch up on work not completed in 2022, and some other minor increases in the portfolio.   |
| Compression Stations                    | 238.5    | 349.6             | 111.1    | The increase of \$111.1M in compression stations is attributed to cost increase of \$118.2M for planned Dawn to Corunna <sup>27</sup> project work in 2023, increase of \$1.2M to repair a failed control valve at Dawn, and \$1.7M increase for Emissions Compliance work; which are partially offset by deferrals of \$2.1M in obsolete control panel upgrades, \$1.3M in replacement of compression auxiliary equipment in the run to failure program, \$0.9M for FIMP, \$3.9M in worn valve replacements, as well as \$1.8M from several other reductions for other smaller investments related to portfolio prioritization. |
| Liquefied Natural Gas                   | 0.8      | 2.0               | 1.2      | The increase of \$1.2M is related to the 2023 pre-spend for an unplanned Hagar compressor overhaul and foundation replacement with execution planned for 2024.   |
| Transmission Pipe & Underground Storage | 280.7    | 97.8              | (182.9)  | The decrease of \$182.9M is related to deferral of \$161.2M for PREP <sup>28</sup> , \$8.9M for the Crowland Wells Upgrade project, \$2.5M in Class Location projects, \$2M from Panhandle Line Replacement, \$3M from Well Lifecycle Replacement, and \$2.1M in A1 Wells replacement and Dow A McPlank Connection. Additionally, a total of \$3.2M in smaller projects has been removed from the forecast during portfolio reprioritization.  |
| Fleet & Equipment                       | 25.5     | 8.8               | (16.7)   | The decrease of \$16.7M is related to identification of \$2.3M in requirements for new tools and equipment offset by savings of \$18.9M from reprioritization for vehicles and equipment purchases.  |

| Asset Class                                 | 2023 AMP       | 2023 9+3 Forecast | Variance      | Variance Explanation   |
|---|----------------|-------------------|---------------|--|
| <b>Real Estate &amp; Workplace Services</b> | 52.1           | 69.6              | 17.5          | The increase of \$17.5M is primarily related to a \$22.1M increase for the SMOC/Coventry (Ottawa Building) Facility project driven by a change to timing for the project. This increase has been partially offset by a \$10.1M reduction to the new Station B building through adjusted pacing of construction and other minor reductions to the forecast. |
| <b>Technology &amp; Information Systems</b> | 63.7           | 44.4              | (19.4)        | The decrease of \$19.4M is related to reprioritization of the TIS Business Solutions portfolio based on business needs resulting in \$20.3M in reductions and deferrals, partially offset by \$3.5M in carryover costs and new investments.  |
| <b>EA Fixed O/H</b>                         | 21.7           | 23.7              | 2.1           | The increase of \$2.1M is related to the inclusion of third-party prework blankets in the EA Fixed Overhead asset class.   |
| <b>Total</b>                                | <b>1,506.0</b> | <b>1,462.1</b>    | <b>(43.9)</b> |  |

This will allow in-line inspection of the pipeline which is required as per the Pipeline Integrity Management Program.<br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30 per cent SMYS. It includes installation costs for permanent inline inspection (ILI) tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections.   | Completed   | Fail | See investment description, IRPAs not applicable  | -   | -                             | -                                     | -  | -                                      | -               |                    |                             |   |

Vintage steel mains have shown signs of declining health due to the cumulative effect of poor, manufactured coating performance; construction practices; latent third-party damages to pipe coating; and the effect of stray currents from transit infrastructure such as subway and streetcars. The current failure projection model is forecasting an exponential increase in the number of corrosion-related failures, while the CSS value framework and the 40-year risk projection are showing an increase in the safety risk associated with steel main failures. Vintage steel systems also have potential to include compression couplings, shallow installation depth and shallow assemblies making pipe susceptible to third-party damage, and manufactured defects associated with seam welds and fittings.  | Completed   | Fail | NPS 2, cannot downsize or retire  | -   | -                             | -                                     | -  | -                                      |                 |                    |                             |   |

Over the years, different materials have been used for this asset, including steel, copper, and varying resins of plastic, each with unique characteristics that contribute to their performance over time. Services can be repaired or replaced depending on asset condition and the nature of the issue exhibited. Generally, replacement is the preferred approach to mitigate unacceptable asset condition.  | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

| Eastern | 60 - Ottawa          | Distribution Pipe     | Pass                         |                      | 101343          | A60: Sparks St, Ottawa, Replacement              | 2026            | \$ 15,013,819                          | Issue/Concern: Sparks Street's NPS 12 steel main is approaching end of life and a replacement is necessary. This main was installed in the 1960s and 1970s and has compression couplings, Dresser-style fittings, drips and blow-off valves. Sparks Street is a pedestrian path through the downtown core of Ottawa with no vehicular access; therefore, performing maintenance activities or accessing the site during emergencies is a challenge. Replacement work is timed ahead of planned third-party road construction work along Sparks and Albert Street that could create third-party damage to these components and result in loss of containment. It will also provide an opportunity to coordinate development and design work with the Sparks Business Improvement Area (BIA) along with planned utility work on Albert Street.<br><br>Assets: Approximately 1,100 m of NPS 12 intermediate pressure (IP) steel pipe on Albert Street, 900 m of NPS 4 Polyethylene (PE) pipe on Sparks Street, and 175 m of NPS 4 PE pipe from Lyons to Wellington.<br><br>Related Programs: Not applicable. | Completed                              | Fail                         | ETEE - Potentially could reduce project scope. | Eastern | 60 - Ottawa          | Distribution Stations | Fail                         | Dollar threshold     | 735165          | 68602A STARTOP DISTRICT XHP                     | 2024            | \$ -                                   | Issue/Concern: EGI has a high pressure (HP) to intermediate pressure (IP) district station located inside a building. The regulator station is located in the garage of a house and is not to current EGI standards. The station is located close to a school, hospital, shopping complex, and dense residential population. The integrity team is planning an inline inspection of the Vital NP5 12 (Network 6582) and additional space is required for a receiver.<br><br>Assets: Station# 68005A<br><br>Related Program(s): N/A<br>Brockville Gate Station is located on EGI-owned property approximately 5 km from the town of Brockville, Ontario. This station accepts natural gas from TC Energy and provides supply to two separate XHP networks. Station components include measurement, gas preheat system, pressure regulation, odourant injection and a telemetry system. This station supplies natural gas to approximately 19,463 customers in Brockville region. The following issues have been identified at this station:<br><br>Pipes, Valves & Others: The existing valves at this site have experienced issues in performance and operation of the valves. Valve maintenance has been unable to remediate the problem and the valves have deteriorated to the point where the reliability is no longer acceptable. All valves will have to be replaced. The inlet of the regulator runs is a challenge every year.<br><br>Heating: The boiler system was replaced in 2019. However, the glycol tank and heat exchanger will need to be replaced and relocated to meet Electrical Safety Authority (ESA) requirements. Residual glycol impacts are to be evaluated and removed as required, as a result of glycol release that was reported from a boiler inside the Boiler building.<br><br>Pressure Control: The regulator station has boot-style regulators posing an undesired higher risk and high associated ongoing maintenance costs. Engineering has identified that boot-style regulators operating as both monitor and operating regulators is unacceptable. The regulator runs will have to be rebuilt.<br><br>Odourization: The odourant system was installed in 2000. A new Odourant building will have to be installed to ensure adequate containment in the event of a leak. The injection pumps are located in the regulator room and will have to be relocated into the Odourant building to meet current standards.<br><br>Telemetry and Electrical: The size of the Remote Terminal Unit (RTU) building is not an issue but the leaky roof is. This building not only houses the RTU but also the St. Lawrence Control Centre (CC) (this is the gas control hub for Leeds, Brockville, Bethel, St. Lawrence, Summerstown and Lancaster Gate stations, as well as International Bridge CDN and USA, and Lisgar). The transfer switch, main panel, and junction box are located in the old RTU room, which is attached to the instrumentation room, but does not violate the Electrical code. Boilers were recently replaced and can be reused as well as the inlet/outlet and tank pressure transmitters. New temperature transmitters and a new tank level gauge are needed. The ultrasonic electronics should be upgraded. The main disconnect should be taken off the Hydro pole and moved to the electrical/RTU room. There should be an upgrade to the CC Uninterruptible Power Supply (UPS) system (specifically for the network switches). The odourant tank is located in an old-style, steel building. The RTU is an older Control Wave Micro (CWM), but could suffice; however, its UPS should be upgraded. There is no boiler room CO detector. The odourant injection system should be separated from the regulators. There is no weather station. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

| Eastern | 60 - Ottawa          | Distribution Stations | Pass                         |                      | 3622            | SUMMERSTOWN GATE                                | 2026            | \$ -                                   | Summerstown Gate Station is located on EGI-owned property of approximately 1,000 m2 fenced compound in South Glengarry Township, Ontario, approximately 16 km from Cornwall, Ontario, within a rural area. This station accepts natural gas from TC Energy and provides supply to an XHP network, through components within the measurement system, pressure control system, heating system, odourant system, and telemetry system. This station feeds 265 customers. The following issues have been identified at this station:<br><br>Valves & Piping: The existing valves at this site have experienced issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable. The existing inlet and bypass valves are flange by flange and have experienced leaks through these flanges. Flanged valves on the station inlets are more prone to leaks and more difficult to repair.<br><br>Odourization: The odourant system was installed in 1998. The current configuration of the odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals.<br><br>Telemetry & Electrical: The existing electrical system does not meet current EGI electrical installation standards. This poses a potential electrical hazard and faulty wiring may result in lost communications.<br><br>Tower: Tower is to be removed as it is not required for SCADA communications.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| Eastern | 60 - Ottawa          | Distribution Stations | Pass                         |                      | 7751            | KEMPTVILLE GATE                                 | 2027            | \$ -                                   | Kemptville Gate Station is located on EGI-owned property of approximately 2,825 m2 fenced compound in the Municipality of North Grenville, Ontario, approximately 37 km south of Ottawa, within a rural area. This station accepts natural gas from TC Energy and provides supply to XHP networks, through components within the Measurement system, Pressure Control system , Heating system, Odourant system, and Telemetry system. This station supplies natural gas to approximately 3,256 customers in the Kemptville area. The following issues have been identified at this station:<br><br>Pipe, Valves & Others: The existing valves at this site have experienced issues in performance and operation. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable.<br><br>Heating: The existing boilers at this site are 22 years old and have reached end of life based on condition review and performance.<br><br>Pressure Control: The Regulation system is installed within a building currently in disrepair with several leaks. The operator and monitor regulators are both double-boot style regulators and are both susceptible to boot failure should they be exposed to significant debris in the system. Repairs have been made where possible but the building continues to deteriorate. Also, the working space inside the building produces an ergonomic/safety risk to EGI employees. This will require addition of filtration or regulation replacement. Furthermore, a new building will be required to address safety/ergonomic issues at the station.<br><br>Odourization: The building has containment but does not meet current standards. There are no issues with the current system.<br><br>Telemetry & Electrical: The Telemetry and Electrical systems do not meet current EGI standards, do not contain backup power supply in the event of power loss, and are approaching end of useful life. The existing Remote Terminal Unit (RTU) is obsolete and is required to be upgraded to current standards along with new communications equipment in order to mitigate cybersecurity threats.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers. This network in Ottawa is predominantly made up of residential and commercial customers. In the current configuration, a high pressure network is exclusively fed by both the Ottawa and Richmond Gate Stations. An upstream flow constraint has been identified at the Ottawa Gate Station, along with a bottleneck constraint for gas fed from Richmond Gate Station. The South outlet of Ottawa Gate can be set to as low as 400 psig (normally 470 psig) while Richmond Gate is kept at 470 psig, thus flowing more gas from the west to the east.<br><br>The current configuration, an existing NPS 12 high pressure pipeline along Fallowfield Road is a bottleneck for gas flowing from the west to Richmond Gate Station, and to eastern areas. The previously constructed Ottawa Reinforcement Plan (ORP) Phase 1 as well as the Strandherd River crossing has helped move gas from Richmond Gate eastward to areas of concentrated and growing gas demand.<br><br>This reinforcement will assist in moving additional gas from Richmond Gate toward the areas that would be serviced by Ottawa Gate, and remove the bottleneck constraint. There were approximately 193,553 customers on the associated networks as of 2016.<br><br>Assets: Existing NPS 12 HP Pipe<br><br>Related Program: Not applicable  | In Progress                            |                              |  |                                       |                             |  |                 |                    |                             |

| Eastern  | 60 - Ottawa          | Customer Connections | Pass                         |                      | 3765            | Area 60 - Residential - Replacement*  | 2023            | \$ 151,051,363                         | <p>Issue/Concern: Residential Replacement refers to a residential replacement customer using a fuel other than natural gas for domestic purposes and is converting to natural gas.</p> <p>Issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGI develops a customer additions forecast using a number of information sources - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long-term plans: EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. EGI reviews the following when determining feasibility - The number of potential new customers - The consumption of natural gas by new customers - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth.</p> <p>Assets: All applicable assets.<br/>Related Program: N/A</p> | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |
| Eastern  | 60 - Ottawa          | Growth               | Pass                         |                      | 7743            | NW 6587 L'Original Reinforcement SRP  | 2025            | \$ 6,691,362                           | <p>Issue/Concern: Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure to maintain the capacity to meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers.</p> <p>• Project Purpose/Need: This reinforcement is to add capacity within legacy Enbridge Gas Distribution's pipe network to:<br/>o Satisfy the current contractually allowable demand of the Large Volume Contract (LVC) customer, which is 6,800 m3/h<br/>o Support customer growth of the downstream High Pressure Polyethylene (HPPE) network This geographic area sits at the eastern tail end of XHP network 6587, which is fed exclusively by Lancaster gate to the southeast.</p> <p>• Pressure Issue/Concern : The minimum system pressure was forecasted to be infeasible by 2020.</p> <p>• Customer Growth Issue/Concern: As of 2017, there are 2,039 customers on this network. Without reinforcement, a forecasted 24 customers may not be able to be added.</p> <p>• Risk If Not Completed: System risk without the reinforcement<br/>o EGI may not be able to satisfy contractual demand of a large-volume customer along with supporting forecasted customer growth<br/>o This network is at the mid-tail end of the East Valley line, with pressures approaching the minimum.<br/>o This XHP system is operating at over 30% Specified Minimum Yield Strength (SMYS). If this line pressure drops below 30% SMYS, this reinforcement will not be sufficient.<br/>o Approximately 1,430 customers would potentially be lost over the winter of 2017 – 2018.<br/>o There are approximately 2,039 customers forecasted to be connected by 2017.</p> <p>Assets (preferred option):<br/>• Station: 62328A set to 80 psig<br/>• Main: - 10 km - NPS 4 XHP main - from County Rd. 17 and Hwy 11 - to Cassburn Rd. and Emerson Rd. - along Hwy 11.</p>   | Completed                              | Pass                         | CNG, ETEE - CNG potentially could defer project scope, ETEE potentially could eliminate (with CNG as bridging solution), reduce or defer project scope.  | In Progress                           |                             |  |                 |                    |                             |
| Eastern  | 60 - Ottawa          | Growth               | Pass                         |                      | 102119          | Brockville Gate Extension             | 2025            | \$ 3,131,604                           | <p>Issue/Concern/Opportunity: Area 60 - the Maitland and Brockville regions are currently served by two Gate Stations (i.e., Brockville and Bethel). The Bethel Gate requires a rebuild to maintain safe and reliable operations; and there is an opportunity to add customers in the region if the network has more capacity.</p> <p>The preferred option is to build a lateral connected to the existing Brockville Network extending to the current Bethel Gate site; a district station would be required along with 3,500 m of pipe. Sixty-two potential customers have been identified along this route. A secondary option is to rebuild the Bethel Gate which will ensure safe and reliable operations but will not allow for the opportunity to connect potential new customers.</p> <p>Justification: Bethel Gate is scheduled for a rebuild in 2023 and the pipeline reinforcement is a second option which has added benefits of customer additions and lower future maintenance costs.<br/>Assets: Bethel Gate Station<br/>Related Program: Not applicable</p>  | Completed                              | Fail                         | Timing - Market based supply side alternatives not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification 5-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard 5-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressured gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion. | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -                                      | -                  |                               |

| Eastern | Div_22 - Kingston    | Distribution Pipe | Fail                         | Dollar threshold     | 734706          | King: Thin Wall and Copper Pipe Replacement (Various Locations in Area) | 2030            | \$ 570,213                             | General: Vintage Steel Replacement Program is a proactive replacement program to renew aging vintage steel pipe assets before reaching their end of life. Vintage steel mains have shown signs of declining health due to the cumulative effect of poor, manufactured coating performance; construction practices; latent third-party damages to pipe coating; and the effect of stray currents from transit infrastructure such as subway and streetcars. The current failure projection model is forecasting an exponential increase in the number of corrosion-related failures, while the C5S value framework and the 40-year risk projection are showing an increase in the safety risk associated with steel main failures. Vintage steel systems also have potential to include compression couplings, shallow installation depth and shallow assemblies making pipe susceptible to third-party damage, and manufactured defects associated with seam welds and fittings.<br><br>Augustus St - Cornwall - Eastern - 1729Vintage steel exhibit increased failures as they age as steel mains are susceptible to external corrosion when barriers of pipe coatings and cathodic protection are compromised. The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (Vintage Steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization<br><br>Comments: Remove York from 5th to 9th streets. The cost sharing for this work is managed through the Franchise Agreements established with municipalities. A consultative approach is used between the municipality and EGI to avoid conflicts with municipal infrastructure early in the planning stage. If a conflict is unavoidable, pipeline assets are typically relocated or replaced.   | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                | -                           |

| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 1011            | SCHOMBERG GATE  | 2024            | \$ 77,497                              | Schomberg Gate Station is located on EGI-owned property of approximately 1,250 m2 fenced compound in the Township of King, Ontario, approximately 3 km from the town of Pottageville, within a rural/urban area, in close proximity to Kettleby. This station accepts natural gas from TC Energy and provides supply to two separate XHP networks, through components within the Measurement system, Pressure Control system, Heating system, Odourant system, and Telemetry system. This station supplies natural gas to approximately 23,501 customers in the King Region. The following issues have been identified at this station:<br><br>Compliance: An engineering assessment of the site layout has identified a conflict with the location of the Telemetry or Boiler buildings with respect to the Electrical Safety Authority (ESA) Area Classification requirements which has identified that an ignition source is in close proximity to a potential leak source, as defined within the Electrical Codes and Standards.<br><br>Measurement: The current system does not provide measurement of the individual outlet supplies. Visibility to each outlet supply provides greater redundancy to the existing measurement and improved response capabilities.<br><br>Valve & Piping: The existing valves at this site have experienced issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable.<br><br>Heating: The existing boilers at this site have experienced trouble call/failures over the recent years, including failures of the motors and pumps, burner lock-outs and exchanger failures. Due to recent and upcoming customer growth in the King area, the existing heating system will not be capable of supplying the heating requirements to meet the demand.<br><br>Pressure Control: The Regulation system is undersized and not capable of supplying the demand required to meet the customer growth in the King area. The configuration of the existing regulators is double boot, posing an undesired higher risk and high associated ongoing maintenance costs.<br><br>Telemetry & Electrical: The existing electrical system does not meet current EGI electrical installation standards. This poses a potential electrical hazard and faulty wiring may result in lost communications.<br><br>Additional Scope: Replacement of 24 m NPS 6 road crossing NW 2103 is required in order to ensure the pipeline does not exceed the required %SMYS to be designated an Integrity Management Program (IMP) main and require retrofit and inspection. The deadline or this replacement is June 11, 2024.   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The existing valves at this site have experienced issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves, however, the valves have deteriorated to the point where the reliability is no longer acceptable<br><br>Heating System: Updated heating is required at this station. New Heat Exchanger is required including the associated piping for the glycol inlet and outlet to heating element. New boiler building will be procured as the existing building is within the ESA classification.<br><br>Pressure Control: Not Required<br><br>Odorant System: New Odorant system is required. This would include a new Odorant building including tank (Assume 500G – Enbridge standard). New Odorant cabinet including 2 new pumps and associated tubing from the tank equipment to cabinet. New sight glass for injection point is required. New odorant building to be outfitting with new electrical distribution and internal/external lighting. Galvanized building stairs to be accounted for.<br><br>Telemetry/Electrical: New Control Wave Micro unit required and associated connections. Account for 1 new pressure transmitter and 1 new temperature transmitter. The telemetry and electrical systems do not meet current EGI standards, do not contain backup power supply in the event of power loss, and are approaching end of useful life. The existing RTU is obsolete and is required to be upgraded to current standards along with new communications equipment in order to eliminate cyber security threats. New Telemetry building will be required to be installed in new compliance location.<br><br>Measurement: No information provided.<br><br>Building: New Odorant Building required (See Odorant Scope for details). Additionally, new boiler building will need to be procured. An engineering assessment of the site layout has identified a conflict with the location of the telemetry or boiler Buildings with respect to the ESA Area Classification<br><br>Compliance/Civil: Minor Site Grading will be required and new crash bar access and 2 sides of site.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 1148            | BATHURST GATE   | 2026            | \$ -                                   | The regulators are heavy and maintenance is difficult in the current arrangement, a lifting device is needed for ergonomic reasons. The current heating system consists of condensing boilers that have condensate which will require mitigation. A conversion to noncondensing boilers is required and during the conversion three-way valves and associated piping (6,000 by Stations Ops) will be added. The front gate experiences flooding and teh grade by the gate needs to be raised because water pools at the main gate.   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 3614            | BOND HEAD GATE  | 2026            | \$ -                                   | Bond Head Gate Station is located on EGI-owned property of approximately 1,900 m2 fenced compound in the village of Bond Head, Ontario, approximately 8.5 km west of Bradford Ontario, within a rural area, in close proximity to several homes. This station accepts natural gas from TC Energy and provides supply to two separate XHP networks and one IP network, through components within the measurement system, pressure control system, heating system, odourant system, and telemetry system. This station supplies natural gas to approximately 60,000 customers in the Alliston, Orangeville, Bradford, and northern York Region. The following issues have been identified at this station:<br><br>Compliance: An engineering assessment of the site layout has identified a conflict with the location of the Telemetry or Boiler buildings with respect to the Electrical Safety Authority (ESA) Area Classification requirements which has identified that an ignition source is in close proximity to a potential leak source, as defined within the Electrical Codes and Standards.<br><br>Valves & Piping: The existing valves at this site have experienced issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable.<br><br>Measurement: The current Turbine meter does not provide measurement of the individual outlet supplies. Visibility to each outlet supply provides greater redundancy to the existing measurement and improved response capabilities. As well, failures have been experienced over the past year including complete meter failure and jamming. Station has a backup orifice plate meter, which has experienced several alarms.<br><br>Heating: The existing boilers at this site are approaching 20 years old, they have had 10 trouble call/failures over the recent years, including failures of the motors and pumps, burner lock-outs and exchanger failures. Due to recent and upcoming customer growth in the Bradford/York Region area, the existing heating system will not be capable of supplying the heating requirements to meet the demand.<br><br>Pressure Control: The regulation system is undersized and not capable of supplying the demand required to meet the customer growth in the Bradford/York Region area. The configuration of the existing regulators are double boot, posing an undesired higher risk and high associated ongoing maintenance costs.<br><br>Odourization: The odourant system was installed in 2003. The current configuration of the odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals.<br><br>Telemetry & Electrical: The existing electrical system does not meet current EGI electrical installation standards, the existing Telemetry building is in poor condition beyond repair. This poses a potential electrical hazard and faulty wiring may result in lost communications. The existing generator and backup supply systems have reached end of life. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

|----------|----------------------|-----------------------|------------------------------|----------------------|-----------------|---|-----------------|--|--|--|------------------------------|---|---------------------------------------|-----------------------------|--|-----------------|--------------------|-----------------------------|
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 3624            | VICTORIA SQUARE GATE                          | 2024            | \$                                     | <p>- Pipe, Valves and Others: Current actuators on the inlet, outlet and heat exchanger valves need to be commissioned and programmed for remote control by Gas Control in the Remote Terminal Unit (RTU). The RTU will have to be upgraded to accommodate the additional input/output (I/O) as its current capacity is full. NPS 8 Becker control valve was replaced in 2016. Fuel gas supply and meter set will be required to replace outdated station.</p> <p>Measurement: The existing Measurement system is scheduled for upgrade in 2019 and it is expected that this work will be sufficient for operation in 2024. No upgrade to the Measurement system is included in this business case.</p> <p>Heating System: Existing Heating system is not in compliance with the Area Classification and will require boiler building relocation. The boilers have recently been replaced and should continue to operate. The boiler building is located in a classified area and will have to be moved and/or remediated. Exhaust fans may resolve the issue but this will be determined in detailed engineering. Heat exchangers were recently inspected (2015/2016) and will not require replacement.</p> <p>Pressure Control: Low flow regulator run was added in 2017. No additional work is required on the regulation runs.</p> <p>Odourant: Install a new Odourant building as the current metallic odourant building is without adequate containment. This building rusts, leaks in rain and spill response is hampered due to difficulty wrapping the building. The tank has bottom connections to feed the injection pumps. Odourant pumps are also in a different building and will be located appropriately in the same building as the 3,500 gallon odourant tank. This tank will have to be upsize.</p> <p>Telemetry/Electrical: RTU replacement is required from an old Bristol 3330 to a new control wave RTU. RTU upgrade is required as the current design has no available expansion capacity to accommodate new actuator, measurement inputs, additional methane and CO sensing. This will require a new RTU building. Electrical Safety Authority (ESA) compliance issues will be resolved by relocating electrical equipment. Upgrades to station wiring will be required to allow for new instrumentation. The electrical service will be upgraded to accommodate the new station loads. A new station grounding network, updated anti-climb tower, and updated instrumentation will be installed to meet current standards. A generator (installed 1999) and UPS system will be installed for backup power requirements in the event of a power outage. A new modem and firewall, improved station lighting, odourant tank instruments, and a weather station will be installed to meet current standards. Electrical upgrades are required.</p>  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 7753            | NOBLETON GATE                                 | 2024            | \$ 75,744                              | <p>Issue/Concern: Nobleton Gate Station is located on a fenced, EGI-owned property of approximately 1,000 m2 in the City of Vaughan, Ontario, approximately 3 km from the Town of Nobleton, within a rural area. This station accepts natural gas from TC Energy and provides supply to an XHP network, with a Measurement system, Pressure Control system, Heating system, Odourant system, and a Telemetry and Controls system. This station supplies natural gas to approximately 1,800 customers in the Bolton and King City areas. The following issues have been identified at this station:</p> <p>Compliance: An engineering assessment of the site layout has identified a conflict with the location of the Telemetry and Boiler buildings with respect to the Electrical Safety Authority (ESA) area classification requirements, which have identified that an ignition source is in close proximity to a potential leak source, as defined within the Electrical Codes and Standards. Additional property will be required to remediate the area classification issue.</p> <p>Measurement: Gas measurement is completed using a turbine meter installed in 2004. This meter type has experienced failures causing potential downstream impacts and loss of service to customers. This meter has experienced six failures in the past two years, due to leaks and faulty measurement. A new mass flow meter will be installed to replace the turbine meter and a backup outlet Annubar meter will also be installed.</p> <p>Heating: The existing boilers at this site are 14 years old. They have had three trouble call/failures over the past year including failures of the motors and pumps, burner lock-outs and exchanger failures. The boilers, building, and glycol piping require replacement as they will be 20 years old by the target rebuild date. The heat exchanger is not expected to be replaced but inspection is to be included.</p> <p>Pressure Control: The regulators are the original regulators installed when the station was first commissioned. In 2001, a building was installed over them to improve maintenance and operation. The regulators have experienced 29 trouble calls/failures in the time period including leaks, boot failures, and pilot failures. Both monitor and operator runs are boot-style regulators, which poses an undesired higher risk and high associated ongoing maintenance costs.</p> <p>Odourization: The odourant system was installed in 2004 with the injection system installed in 2009. The current configuration of the odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals. The panel will have to be relocated into a new building with a larger new tank. Upgrade of odourant system (condition of containment and unsafe grating in the building for access) is to be included in refreshed scope – 500 GAL odourant system. A new Odourant building is required including new concrete foundation. Building is to be equipped with all electrical requirements. Building is to be equipped with new steel platform for Operations and Maintenance (O&amp;M) activities including delivery. New sight, glass radar gauge equipment must be provided. Scope is to account for decommissioning and commissioning of the new odourant system.</p> | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 7769            | KEELE AND STEELES/CNR FEEDER                  | 2023            | \$                                     | <p>- Keele and Steeles/CNR Feeder Station is located on 3,000 m2 compound in the city of Vaughan, Ontario, approximately 1.5 km from York University, within an urban area in close proximity to CNR Railway Corridor. This station accepts natural gas from EGI XHP pipeline and provides supply to three separate XHP networks and an HP network, through components within the Pressure Control system, Heating system, Odourant system, and Telemetry system. This station supplies natural gas to approximately 20,000 customers in Vaughan and Toronto area. The following issues have been identified at this station:</p> <p>Valve &amp; Piping: the existing valves at this site have experienced 10 failures and leak issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable.</p> <p>Pressure Control: The configuration of the existing regulators was installed in 1990 and is double boot, posing an undesired higher risk and high associated ongoing maintenance costs. The existing regulators have reached end of life.</p> <p>Telemetry &amp; Electrical: The Telemetry and Electrical systems do not meet current EGI standards, do not contain backup power supply in the event of power loss, and are approaching end of useful life. The existing Remote Terminal Unit (RTU) is obsolete and is required to be upgraded to current standards along with new communications equipment in order to eliminate cybersecurity threats.</p>  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The existing Remote Terminal Unit (RTU) is obsolete and is required to be upgraded to current standards along with new communications equipment in order to eliminate cybersecurity threats.</p> <p>Measurement: Not required.</p> <p>Building: New Odourant building is required</p> <p>Compliance/Civil: Minor site grading, new crash bar access and two sides of site will be required.</p>   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA East | 30 - Richmond Hill   | Distribution Stations | Pass                         |                      | 8567            | St. John's Sideroad Feeder Station Relocation | 2023            | \$ 11,966,881                          | <p>Issue/Concern: The property on which St. John's Sideroad Feeder Station currently sits is insufficient for operation. It is located adjacent to a residential property and the area classification extends onto the adjacent private property. The Boiler building is located in a hazardous area classification and the non-compliance needs to be remedied. Road widening of St. John's Sideroad currently has the sidewalk encroaching on our station. A land sale agreement with York Region was completed in 2016 and requires movement of the electrical meter.</p> <p>As the area classification issue risks shutdown of the station by the Electrical Safety Authority, EGI is planning to resolve the movement of the electrical meter (on site) pending a new land purchase for relocation of the entire station. As a result of station relocation, a complete rebuild will be required. Maintenance on the Boiler system piping, pumps and gauges, which are old and obsolete, suggest that the Heating system needs to be replaced regardless of station relocation. The Heating system is already undersized for the current demand. The FL regulators are difficult to work on due to their weight and ergonomic restrictions in a cramped building. These are to be replaced and upgraded. The old Remote Terminal Unit (RTU) 3330 Telemetry system needs to be upgraded, including the backup power generator which is old and obsolete. The station was updated in 2006 and a new generator and boilers were installed in 2003. Source records do not indicate any regulator capacity issue.</p> <p>Asset: Stn ID: 2944180</p> <p>Related Programs: Not applicable.</p>   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

Issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGO develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long term plans EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. Enbridge reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers and, - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing Assets: Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth   | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification S-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard S-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressured gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion. | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  |                             |

| GTA East | 40 - Whitby          | Distribution Stations | Pass                         |                      | 7749            | BOWMANVILLE GATE                                | 2026            | \$ -                                   | <p>Issue/Concern: Bowmanville Gate Station is located on fenced EGI-owned property of approximately 700 m2 in Clarington, Ontario. It is approximately 5 km north of Newcastle Ontario, within a rural area. This station accepts natural gas from TC Energy and provides supply to two separate XHP networks, through a measurement system, pressure control system, gas pre-heat system, odourant injection system, and telemetry and controls system. This station supplies natural gas to approximately 61,000 customers in an area that spans from Bowmanville to Lindsay. The following issues have been identified at this station:</p> <p>Valves and Piping: The existing valves at this site have experienced issues in performance and operation of the valves. Maintenance has been performed to attempt to remediate the valves; however, the valves have deteriorated to the point where the reliability is no longer acceptable. The inlet piping to the heat exchanger shows signs of deterioration and should be replaced. The station is located close to Hwy 35/115 and its proximity to traffic puts it at a higher risk. The piping is to be relocated away from the road, as far as practical.</p> <p>Measurement: The current system does not provide measurement of the individual outlet supplies. Visibility to each outlet supply provides redundancy to the existing measurement, odourant injection reliability, and improved response capabilities. The turbine meter is to be replaced with a Coriolis meter.</p> <p>Heating: The existing boilers at this site are 18 years old, they have had 42 trouble call/failures over the life of the heating system, including failures of the motors and pumps, burner lock-outs and exchanger failures. The system, including buildings, will require replacement as it approaches end of life.</p> <p>Odourization: The odourant system was installed in 1999. The current configuration of the odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals. The building is an old-style, rusted metallic odourant building without adequate containment and a new building, tank, and Odourant Injection system will be required.</p> <p>Telemetry and Electrical: The existing Electrical system does not meet current EGI electrical installation standards. This poses a potential electrical hazard and faulty wiring may result in lost communications.</p> <p>Other: Odourant deliveries - a third-party company is used for traffic control during deliveries. Additional land, not included in this business case, may be identified under a separate business case for station expansion to improve safety during odourant deliveries off of Hwy 35/115.</p> <p>Asset: Bowmanville gate station assets.</p> | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

Issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGD develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long term plans EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. Enbridge reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers; and, - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing Assets: Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth</p>   | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |

Each year, EGI develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long-term plans: EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. EGI reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth.</p> <p>Assets: All applicable assets.</p> <p>Related Program: N/A</p>   | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification S-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard S-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressurized gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion.   | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

Over the years, different materials have been used for this asset, including steel, copper, and varying resins of plastic, each with unique characteristics that contribute to their performance over time. Services can be repaired or replaced depending on asset condition and the nature of the issue exhibited. Generally, replacement is the preferred approach to mitigate unacceptable asset condition.  | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                | -                           |

This station accepts natural gas from EGI XHP pipeline and provides supply to an IP network, through components within the Pressure Control system, and Telemetry system. This station supplies natural gas to approximately 10,000 customers in the City of Mississauga. The following issues have been identified at this station:<br><br>Valve & Piping: The piping material and components used within this station have been identified as sub-standard with improper construction methods used during construction.<br><br>Pressure Control: The configuration of the existing regulators is double boot, posing an undesired higher risk and high associated ongoing maintenance costs.<br><br>Telemetry & Electrical: The Telemetry and Electrical systems do not meet current EGI standards and are approaching end of useful life. The existing Remote Terminal Unit (RTU) is obsolete and is required to be upgraded to current standards along with new communications equipment in order to eliminate cybersecurity threats. Additionally, new instrumentation, a lighting upgrade, and a tower upgrade which is compliant based on space available is required.   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West | 20 - Mississauga a   | Distribution Stations | Pass                         |                      | 7777            | WINSTON CHURCHILL AND STEELES FEEDER                | 2024            | \$ 9,650,063                           | Winston Churchill and Steeles Feeder Gate Station is located on EGI-owned property fenced compound in Mississauga, Ontario, approximately 4 km from Meadowvale town centre, within a rural area in close proximity to industrial establishments. This station accepts natural gas from EGI XHP and provides supply to two separate XHP and HP networks, through components within the Pressure Control system, Heating system, and Telemetry system. This station supplies natural gas to approximately 20,000 customers in Mississauga and Brampton area. The following issues have been identified at this station:<br><br>Telemetry & Electrical: The Telemetry and Electrical systems do not meet current EGI standards, do not contain backup power supply in the event of power loss, and are approaching end of useful life. The existing Remoter Terminal Unit (RTU) is obsolete and is required to be upgraded to current standards along with new communications equipment in order to eliminate cybersecurity threats.   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West | 20 - Mississauga a   | Distribution Stations | Pass                         |                      | 503369          | Lisgar Station                                      | 2025            | \$ 10,259                              | Issue/Concern/Opportunity: The Lisgar Gate Station is located at a highly populated area in the City of Mississauga. The station is situated in an urban setting and is surrounded by residential buildings, a commercial plaza, and a church. The station has multiple feeds (two transmission lines and one XHP CER line) and various outlets to the local distribution networks. In the event of a major incident, the consequence would be significant given the close proximity to houses and buildings.<br><br>Justification: The following issues and deficiencies have been identified:<br>Pipes & Valves: They have been deemed unreliable at this site and require removal and installation of new pipes, fittings, and valves. The increased load demand will also allow the pipe to be upsized for current and future expansion.<br>Heating: The Heating system has been deemed unreliable as it has reached its end-of-life cycle usage. The placement of the heat exchangers in the basement of the Boiler building has caused maintenance roadblocks along with flooding concerns.<br>Pressure Regulation: The 20002A regulation has been deemed unreliable and will be rebuilt because of inconsistent flows throughout. The 20002D has suffered from frost-heaving issues as well and requires a rebuild.<br>Odourization: The Odourant system's current configuration does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals. The pumps need automation along with redundancy for better operational efficiency.<br>Building: The Regulator building that houses 20002B and 20002C needs a noise evaluation study to determine a better noise attenuation solution.<br>Measurement: Existing measurement is not reliable and accurate. A more robust and accurate measurement needs to be installed for custody transfer purposes.<br><br>Assets: Distribution Station Assets at the Lisgar Gate Station.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West | 20 - Mississauga a   | Distribution Stations | Pass                         |                      | 735335          | GTAW Parkway Gate Station Rebuild Phase 2           | 2024            | \$ 10,544,848                          | Related Program: AFF - 219 - NPS 24 Lisgar to Pine Valley - permanent launcher support (23192)<br>Project: Parkway East Phase 2. Phase 1 commenced in 2021.<br><br>Issue/Concern/Opportunity: The following sub-assets will be rebuilt due to the issues described below:<br><br>Regulators: Two existing Becker control valves, i.e., NPS-8 and NPS-5 downstream operators – PRV-0502 and PRV-0504, Runs 9 and 10 on TC Energy feed (quantity is two) are defective and will not lock-up; therefore, replacement is required. Currently, the inlet valve from the TC Energy feed is used to completely shut off the TC Energy feed; otherwise, the control valves will bleed by and affect nominations in the summer, automated TC Energy inlet valve for emergency shutoff from TC Energy, as well as to ensure inlet valve is closed to avoid bleed by of Becker control valves in summer conditions (CLOSE ONLY VALVE). Flow control valves on the TC Energy feed are Fairchild's (will replace with DNGPs – RUNS 9/10) not a computer-controlled regulator and do not sense downstream pressure. Isolation valves for each run are operational. DNGP should also replace Fairchild for 12-inch Union East – CV replacement (12-inch closest to Boiler building - RUN 1); 4th Fairchild is on the MSL – not required – disconnect and replace with VRP pilot (pressure control only due to downstream system operation). The station can be down to facilitate work as system can be fed from Parkway West. An additional five Jordan motors that are obsolete are to be replaced with Rotork motors (quantity is five). Due to capacity constraints and designing for future flow provided by Distribution Optimization Engineering (DOE) / TSP, Run 1 T4 Becker is to be replaced with T1 Becker (NPS 12). Run 3 has undersized isolation valves (currently NPS 8) and will need upsizing to NPS 16.<br><br>Civil: There is no urethane layer between the pipe support cradle and the bottom of the pipe. A single new Odourant building is required. The wall between the Pressure Transmitter and Remote Terminal Unit (RTU) room is to be opened up for entire building to be RTU room. Demolition of existing Generator building is required. The Storage building is to be removed due to end of life.<br><br>Piping & Valves: An increase in pipe size near heaters to NPS 30 along with inlet/outlet HX valves to ensure flow requirements can be achieved. Upsizing downstream header and inlet pipe to regulators to NPS 30 is required to ensure it can handle capacity requirements.<br><br>Odourant: The Odourant system is a metallic odourant building without adequate containment with a rusted containment pan. The fill connection is outdoors. Supports are not fire-rated and no Fire Suppression system is installed. Grating within the building is not safe for accessing valves and equipment. A new Odourant building is required. Two 5,000 GAL odourant tanks complete with electric pumps are to be installed. Low-flow and high-flow pumps with full redundancy on winter pumps on each outlet are required. Switchover between pumps should be automated. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

Additional electrical wiring and cabling (including power distribution) and programming are required.<br>Apartment - An apartment customer is a multi-residential dwelling containing more than six units that is bulk-metered/issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGD develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long term plans EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. Enbridge reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers; and - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing Assets: Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth   | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |

Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGI develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long-term plans: EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. EGI reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth.<br><br>Assets: All applicable assets.<br>Related Program: N/A                 | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. | GTA West | 20 - Mississauga     | Growth            | Pass                         |                      | 16748           | Erin IP System Reinforcement                        | 2028            | \$ 6,130,973                           | <p>Issue/Concern: Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure, maintain capacity, and meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers.</p> <p>• Project Purpose/Need: The purpose of Phase 1 main reinforcement is to provide capacity on the east side of district station RS21100A, Erin District along Main St. and improve the degrading pressures. Phase 2 and 3 will provide capacity and will improve the degrading pressures southwest of the station along Trafalgar Rd.</p> <p>• Pressure Issue/Concern: The minimum system pressure is 10 psi and is forecasted to be infeasible by 2019 (when the first phase is proposed to start).</p> <p>• Customer Growth Issue/Concern: As of 2018, there are 2,039 customers on this network. Without reinforcement, a forecasted 866 customers may not be able to be added.</p> <p>• Risk if Not Completed: At its current condition, the system will not be able to supply gas for large load additions (i.e., subdivision and commercial) as per the Long-Range Plan (LRP) projections since existing mains have limited capacity and pressures below the minimum system pressure. As per model results, in years 2019, 2023, and 2025, pressures were below minimum system pressures.</p> <p>Assets (preferred option): Phase 1 Year 2019 - Upsize approximately 2,600 m existing NPS 4 ST/PE to NPS 6 PE on Main St. (Station RS21100A, Erin District to Wellington Rd. 124).</p> <p>•2021 Updates: Phases 2 and 3 have been deferred to 2027 and 2028.<br/>oPhase 2 was deferred to 2027 from 2023 - Upsize approximately 3,100 m existing NPS 4 ST to NPS and PE on Sideroad 17 (Station RS21100A, Erin District to Wellington Rd. 24).<br/>oPhase 3 was deferred to 2028 from 2025 - Upsize approximately 5,000 m existing NPS 4 ST to NPS and PE on Wellington Rd. 24 (Sideroad 17 to Orangeville St.).</p> <p>Related Programs: Not applicable.</p> | Completed                              | Fail                         | N/A - Project Completed                                       | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West | 20 - Mississauga     | Growth            | Pass                         |                      | 17243           | NW 2225 Terra Cotta IP Reinforcement SRP            | 2028            | \$ 1,712,281                           | <p>Issue/Concern/Opportunity: Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure to maintain the capacity to meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers.</p> <p>•Project Purpose/Need: The Long-Range Plan (LRP) load growth is on the Northwest of the district station RS21221A, King and Creditview District. Because of its collateral impact , the pressures at Mill St. are degraded to below minimum system pressure (MSP) due to less NPS 2 PE main capacity and distance from the NPS 4 PE main source.</p> <p>•Pressure Issue/Concern: The minimum system pressure is 10 PSI and was forecasted to be infeasible by 2021. Customer growth issue/concern: In 2017, there are 352 customers on this network. Without reinforcement, forecasted 26 customers (2018-2028) may not be able to be added.</p> <p>•Risk if Not Completed: Per model results, pressures on Mill St. will be below the MSP, if the NPS 4 PE main is not installed.</p> <p>•Project Benefits: Installing an NPS 4 PE main on Mill St. will mitigate the deteriorating pressures with the projected yearly load growth on the Northwest of the district station RS21221A, King and Creditview District comes in.</p> <p>Assets (preferred option):</p> <p>•Phase 1 Year 2021 - Install approximately 1,700 m of NPS 4 PE on Mill St. (Creditview Rd. to Mississauga Rd.) .</p> <p>•Phase 2 Year 2030 - Install approximately 1,300 m of NPS 4 PE on Mill St. (Mississauga Rd. to Caledon Trailway Path, then along Caledon Trailway Path to Heritage Rd.).</p> <p>Assets: Pipe</p> <p>Related Program: Not applicable</p>   | In Progress                            |                              |   |                                       |                             |  |                 |                    |                             |

The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification S-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard S-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressured gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion.</p>   | Completed                              | Fail                         | See investment description, IRPAs not applicable              | -                                     | -                           | -                                      | -               | -                  | -                           |

| GTA West | 50 - Barrier         | Distribution Stations | Pass                         |                      | 7756            | RUGBY GATE                                    | 2025            | \$ 32,290                              | Rugby Gate Station is located on EGI-owned property of approximately 1,350 m2 fenced compound in the Township of Oro-Medonte, Ontario, approximately 7 km from Orillia, within a rural area. This station accepts natural gas from TC Energy and provides supply to an XHP network, through components within the Measurement system, Pressure Control system , Heating system, Odourant system, and Telemetry system. This station supplies natural gas to approximately 20,000 customers in the Coldwater, Midland area. The following issues have been identified at this station:<br><br>Measurement: The current system does not provide measurement of the individual outlet supplies. Visibility to each outlet supply provides greater redundancy to the existing measurement and improved response capabilities.<br><br>Valve & Piping: The existing piping within this station have been assessed to be in poor corrosion condition with identified degradation of the piping.<br><br>HEATING: the existing boilers at this site are 16 years old, they have had 5 trouble call/failures over the past year including failures of the motors and pumps, burner lock-outs and exchanger failures. Due to recent and upcoming customer growth in the Barrier area, the existing Heating system will not be capable of supplying the heating requirements to meet the demand.<br><br>Odourization: The Odourant system was installed in 2003. The current configuration of the Odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals.<br><br>Telemetry & Electrical: The existing Electrical system does not meet current EGI electrical installation standards. This poses a potential electrical hazard and faulty wiring may result in lost communications.<br><br>Compliance: The existing Boiler building is located within a hazardous area and will have to be relocated.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West | 50 - Barrier         | Distribution Stations | Pass                         |                      | 7758            | THORNTON GATE                                 | 2025            | \$ -                                   | Pipe, Valves & Others: Minor station piping is required for this project scope. The existing Piping and Valve system is in good shape. Due to the reconfiguration for the Heating system, minor station piping may be required to align the new equipment.<br>Issue/Concern:<br>Heating System: Updated heating is required at this station. A new heat exchanger is required including the associated piping for the glycol inlet and outlet to the heating element. New boilers can fit within the limits of the existing building. New modulating boilers are required.<br>Pressure Control: New regulation is required to various flow ranges. New Becker regulators and two runs are required. One monitor and one operator is needed for two runs. This will involve new spools for both runs at a minimum.<br>Odourant System: No changes are required.<br>Telemetry/Electrical: New Control Wave Micro unit and associated connections are required. One new pressure transmitter and one new temperature transmitter are to be accounted for.<br>Measurement: Annubar is sized correct. There is no requirement for replacement.<br>Building: A new Remote Terminal Unit (RTU) building is required (concrete pre-cast building). The existing RTU building is to be removed.<br>Compliance/Civil: Site grading will be required as well as new security fencing (galvanized) including new swing gate and crash bar access.<br><br>Scope:<br>Heating System: Updated heating is required at this station. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGI develops a customer additions forecast using a number of information sources:- Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long-term plans: EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. EGI reviews the following when determining feasibility:- The number of potential new customers - The consumption of natural gas by new customers - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Generally, there are three components of capital investments needed to support customer addition requirements:- Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth.<br><br>Assets: All applicable assets.<br>Related Program: N/A | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification 5-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard 5-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressured gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion.</p>  | Completed                              | Fail                         | See investment description, IRPAs not applicable            | -                                     | -                           | -                                      | -               | -                  | -                           |

| GTA West | Div_17 - Halton      | Distribution Stations | Pass                         |                      | 735054          | HALT: Burlington Gate, boiler                      | 2028            | \$ 2,724,880                           | <p>Issue/Concern/Opportunity:</p> <p>VALVE &amp; PIPING: Piping is experiencing corrosion and will be evaluated by FIMP closer to the proposed project date. FIMP will assess the existing valves for any issues in performance and operation.</p> <p>FILTRATION: N/A</p> <p>HEATING: the existing boilers at this site have reached end of life based on condition review and performance. The building is in disrepair and will be replaced in this investment.</p> <p>This investment aligns with the obsolete heating system strategy that targets stations with heating equipment that have reached end of life, with a focus on systems where there is a risk of a glycol spill. Natural gas heating equipment is used in many System and Customer Stations to help mitigate failure of equipment due to the freezing of liquids in the gas stream and moisture surrounding buried piping. Over many years of operation, a variety of heating systems have been used, resulting in varying equipment age and ultimately, equipment obsolescence. This work will maintain system reliability, ensure operating costs for heating systems are minimized and reduce the potential for glycol spills, including providing the appropriate containment systems to minimize the impacts of an event.</p> <p>Loss of the heating system function could result in two scenarios, (1) frost heave or (2) pressure control failure due to the freezing of station components. Frost heave occurs when the gas is cooled due to the pressure reduction and causes an upward swelling of soil around public or private property near the gas main. Freezing of station components such as creating large ice buildup around valves can prevent operation if gas isolation is required. This could result in the loss of pressure control and potentially lead to an overpressure or underpressure situation. The financial impact includes commodity loss, service disruptions, increased network leak surveys and system checks, repairs or replacement of company-owned property, or damages caused to public, commercial or industrial property. Inoperable systems will lead to a failure to maintain operational supply to customers.</p> <p>PRESSURE CONTROL: Obsolete design will be replaced in this investment.</p> <p>ODOURIZATION: Current system is in working order.</p> <p>TELEMETRY &amp; ELECTRICAL: the telemetry and electrical systems do not meet current EGI standards, do not contain backup power supply in the event of powerloss, and are approaching end of useful life.</p> <p>MEASUREMENT &amp; COMPLIANCE &amp; OTHER Eng: will be assessed closer to project date. Signage and site assess (fencing/egress) to be upgraded during this project.</p> <p>Assets: 18X-601</p> <p>Related Program: N/A</p> | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The purpose of this program is to gain a more complete level of pipeline risk by making additional pipelines accessible for inline inspection. Specific pipelines for retrofit will be identified 1-2 years prior to year of construction. General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30 per cent SMYS. It includes installation costs for permanent inline inspection (ILI) tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections. | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

These surveys may identify locations where remediation is required. The current cycle of depth of cover surveys will be completed in 2023 at which time a prioritized list of capital replacements will be created to plan for any identified required remediation.   | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| Head Office Support | Div_54 - Head Office Support | Distribution Pipe | Pass                         |                      | 49938           | MOP Verification Replacement Program*    | 2029            | \$ 50,195,483                          | Maximum Operating Pressure (MOP) verification is the process of reviewing all existing records for a pipeline system and confirming the maximum operating pressure of pipelines that are greater than 30 percent SMYS. While this is not currently mandated by code in Canada, it is required in the United States and is expected to become a requirement in Canada in the future. Given the number of pipelines greater than 30 percent SMYS, MOP verification will continue to be a multi-year project requiring a dedicated team to complete the verifications and determine if any pipeline remediation is required.<br><br>This forecast includes the costs of replacing sections of pipelines as identified through the MOP verification work. MOP verification was also included in the 2017 customer engagement survey, while 43 per cent of those surveyed recommend waiting for regulation requirements to keep costs down, 40 per cent recommend proactively implementing industry standard. Spreading the verifications over several years will keep costs down and proactively implement an industry standard, which provides additional support for this program. Starting this program as forecast will mitigate the need for higher expenditures in a shorter time frame to meet these expected future mandated requirements. | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

EGI promotes the use of natural gas to these customers as an alternate fuel source to provide a lower-cost and lower-emission fueling solution for vehicles such as garbage trucks, light duty vehicles, and transit buses. Business Development is responsible for the installation, maintenance, and the safe and continued operation of NGT stations assets for these customers. NGT stations differ in operation from distribution system stations as NGT stations use and store compressed natural gas (CNG) on site at up to 4000psi. EGO has two general categories for NGT station types: Large, Mobile and Utility NGT stations and Small NGT stations (also referred to as VRAs). Large, Mobile and Utility NGT stations are similar in operation and will be evaluated for condition in the same manner. Issue/concern: This is a centrally managed program in the Union rate zone to apply high performance paint to stations where existing paint has begun to fail or wear off of the facilities on which it has been applied. The Station Painting Program is a significant corrosion mitigation practice. The frequency and criteria for high performance painting at station sites is specifically prescribed in the Corrosion Control Standard Operating Practice (SOP) and is its documented and committed practice on its compliance with the applicable codes for corrosion control on above-grade station assets. This work will improve compliance and ensure the safety and reliability of EGI assets by reducing the risk of leaks and piping and/or equipment failure due to significant corrosion. | Completed                              | Fail                         | See investment description, IRPAs not applicable         | -                                     | -                           | -                                      | -               | -                  | -                           |

The strategy for the FIMP program is to perform inspections using with approved technologies used at EGI or other utilities for similar asset types. These inspections will assess the condition of existing station assets and will detect any concerns or issues to help determine the likelihood and consequence of failure of individual components and evaluate the risk. This strategy will allow for targeted replacement and will extend the useful life of assets by identifying condition issues prior to the occurrence of an incident. When analysis indicates that ongoing repair costs are likely to exceed capital requirements to replace the asset, the mitigation strategy is evaluated to ensure that risk is managed to the lowest practicable level.   | Completed                              | Fail                         | See investment description, IRPAs not applicable         | -                                     | -                           | -                                      | -               | -                  | -                           |

Additionally, performance capability will be added by installing heat tracer lines, heated cabinets, improved tank valves and indoor regulator panels. This work will help to ensure safe, compliant and continuous odorization. This forecast will help mitigate the risk of tank rupture, frequent freeze off and nuisance odour calls.   | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

A malfunctioning Farm Tap regulator has the potential to create downstream hazards. A failure of the regulator set could potentially cause a higher than acceptable pressure entering the customer's premise. This over-pressure can result in downstream customer appliances failing, loss of containment inside the premise, fire, and explosion. The Farm Tap consists of the inlet/outlet riser, a regulator, and a relief. The condition of the Farm Tap population is largely unknown. As they are installed away from the premise and near the property line, they are exposed to more elements originating from the roadway. Their placement can also make them susceptible to third party damage from maintenance equipment and vehicles. Farm Taps have not been part of pro-active inspection programs. They historically have not been included in MXGI regulator exchanges.<br>2021 DIMP survey for LUG - potential for some immediates | Completed                              | Fail                         | See investment description, IRPAs not applicable         | -                                     | -                           | -                                      | -               | -                  | -                           |

This presents an opportunity to grow EGI's natural gas vehicle (NGV) rental refueling business and promotes the use of natural gas to customers as an alternate source for fueling cleaning machines, forklift trucks, and individual light-duty vehicles at a lower cost, reducing fuel handling cost with lower emissions. By providing NGV Vehicle Refueling Appliance (VRA) equipment to customers on a rental basis, EGI can achieve growth in the marketplace, while fully recovering costs.<br><br>Assets: There are currently over 200 VRA customers that EGI is successfully servicing, including City of Toronto, City of Ottawa, other small city arenas and some private customers.<br><br>Related Program (if applicable): Not applicable.   | Completed                              | Fail                         | See investment description, IRPAs not applicable         | -                                     | -                           | -                                      | -               | -                  | -                           |

Some of the known sites are discovered during the annual Depth of Cover Survey, while others are reported by company crews when performing maintenance work by or 3rd party . At this time the specific work scope of each year is not defined and this is a blanket program as a placeholder in the budget. The mitigation work will include the construction costs from sites identified and planned for the current year, as well as work on sites that are newly identified. Scope of work can vary from small remediation projects to add fill, concrete or bank stabilization, to short replacement of pipe.                                       | Completed  | Fail   | See investment description, IRPAs not applicable   | -  | -  | -  | -  | -                  | -                           |   |   |   |
| Head Office/All | 01 - All             | Distribution Pipe     | Fail                         | Dollar threshold     | 102760          | 2025 Integrity Dig Program*                      | 2025            | \$ 764,542                             |  | Financial tracking will be done on the individual Blanket Anode project to provide financial reporting per area. Justification: The Corrosion Department conducts pipe to soil readings each year on our steel pipelines. When they identify a corrosion area that has fallen below our minimum specifications, they process an order for a anode installation which is completed. The capital request is for 12 months. Engineering has confirmed the Anode Installation as a compliance project. The Corrosion Prevention Program consists of the annual anode replacement to ensure the steel main system is receiving sufficient cathodic protection. The Program utilizes pipe-to-soil survey results to determine which steel main networks require additional or replacement anodes to improve the level of cathodic protection. In addition to active steel mains, the Corrosion Prevention Programs also cover the corrosion control on steel casings. This program is for recoating work and hanger repair.<br><br>Justification: The integrated Corrosion Operating Standard ST-17-813A-DDA9 was released November 25, 2022 and requires the following surveys: Annual visual and 5-year detailed. The standard outlines the following time frames:<br>•Bridge crossing – replace per Engineering assessment per project plan<br>•Bridge crossing – replace expansion joint / Ins flange within 24 month<br>•Bridge crossing – paint pipe / repair hangers / replace casing end seal within 12 months.   | Completed  | Fail   | See investment description, IRPAs not applicable   | -  | -  | -  | -                  | -                           | - |   |   |
| Head Office/All | 01 - All             | Distribution Pipe     | Pass                         |                      | 733993          | 2031 Integrity Dig Program*                      | 2031            | \$ 3,923,719                           | General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30 per cent SMYS. It includes installation costs for permanent inline inspection (ILI) tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections. |  | Completed  | Fail   | See investment description, IRPAs not applicable   | -  | -  | -  | -                  | -                           | - |   |   |

This can be achieved by adopting and continuously upgrading their NGV equipment as part of the maintenance strategy. By upgrading major NGV equipment, EGI can extend the life cycle of the equipment, resulting in a more cost-effective way of operating the NGV stations. Assets: There are a number of current NGV stations EGI maintains  | Completed                              | Fail                         | See investment description, IRPAs not applicable for CNG | -                                     | -                           | -                                      | -               | -                  |                             |
| Head Office/All | 01 - All             | Distribution Stations | Pass                         |                      | 9553            | NGT Maintenance Capital for company/fleet NG refueling stations (2021 to 2032)* | 2028            | \$ 4,095,274                           | Maintenance capital for refueling stations for EGD NGT Fueling stations only Issue/concern: The EGD Fleet department can achieve fuel cost savings and reduced emission benefits by operating the 800-plus fleet vehicles on natural gas versus diesel or gasoline. This presents an opportunity for the EGD Fleet Department to realize fuel savings and promotes the use of natural gas to other fleet operators as an alternate source for fueling vehicles at a lower cost with lower emissions. By demonstrating the use of natural gas, EGD can achieve growth in the marketplace, while realizing fuel savings. Assets: EGD currently operates 19 Natural Gas Vehicle (NGV) fueling stations on company yards. The stations includes; Arnprior Yard, Barrie Yard, Beamsville Yard, Thorold Office, Brampton, Brockvill yard, Ottawa Office, Kelfield yard, Kennedy Road Yard, Midland Gate Station, Oshawa Office, Port Colbourne Yard, Peterborough yard, Shelburne Gate Station, South Merivall, Station B, Stayner Gate Station, Enbridge Training Centre, and the VPC Office. In addition, EGD will installing two new NGT stations to fuel recently converted vehicles and dedicated light duty trucks. These two new stations (Tecumseh Storage facility and Tallman Truck Center (Kemptonville)) will also, need to be maintained. The Telemetry system includes communication paths from the instrumentation at our stations to Gas Control and it allows them to monitor EGI Distribution conditions. Gas flow: For gas supply to meet nominations Leak detection: Indicated by large pressure drops Overpressure protection and Pressure Control: Condition monitoring equipment by gas control ensures gas delivery to the customers in a controlled and safe manner. Included in this program are upgrades to the Telemetry network that include: 1)Cyber Security - Ongoing upgrades to Scada system to ensure compliance with EI Cyber security standards and proposed CSA code. 2)Legacy equipment - 3330 Bristol units(101/yr) must be replaced with Control Wave Micro units 3) RTU Programming Manual - Development of manual detailing programming standards for design, security and expansion 4)SCADA - Development of maintenance layer of Scada to allow site reporting of gas consumption for boiler gas, odourant pump strokes and usage tracking, boiler diagnostics, remote engineering and automation of gate/feeder stations 5)Broadband Communication - Development of broadband links between major stations to support security (i.e. intrusion detection)  | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| Head Office/All | 01 - All             | Distribution Stations | Pass                         |                      | 101556          | 2029 District Station Rebuilds Program* | 2029            | \$ 9,200,653                           | Issue/Concern: The stations identified in this business case fall into one of the following categories: Below-ground box replacements: Removal of below-ground stations improves life cycle cost of stations due to accelerated corrosion related to salting and flooding, increased O&M costs related to increased paint frequency, and the requirement for two at a box when work is performed. An additional and very important benefit to the elimination of below-ground boxes is the improvement of worker health and safety by eliminating the need to handle potentially contaminated water, and non-ergonomic work conditions. Obsolete Regulators: The criteria for this category is that there are no spare parts available, or parts are no longer approved for use on new installations, or a combination of poor performance and manufacturer availability. Low Pressure Districts: The failure of a low pressure district can have disastrous downstream impacts in the event of over-pressure protection failure. The outlets of these stations feed customers who may not have individual regulators at their meter sets. This additional line of defense is not present to protect customer piping. Double Boot-style Regulators: Stations with both operator and monitor boot-style regulators have a common failure mechanism as a result of debris in the gas stream. Replacement of one boot-style regulator with a non-boot regulator reduces the vulnerability of failure. Increased Capacity: Stations that are operating over designed capacity due to system growth are targeted for replacement to maintain gas supply. Loss of Containment: Station experiencing loss of containment (leaks) and high maintenance calls to repair equipment are also identified for replacement. Asset: District station assets Related Program: N/A | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The strategy for the FIMP program is to perform inspections using with approved technologies used at EGI or other utilities for similar asset types. These inspections will assess the condition of existing station assets and will detect any concerns or issues to help determine the likelihood and consequence of failure of individual components and evaluate the risk. This strategy will allow for targeted replacement and will extend the useful life of assets by identifying condition issues prior to the occurrence of an incident. When analysis indicates that ongoing repair costs are likely to exceed capital requirements to replace the asset, the mitigation strategy is evaluated to ensure that risk is managed to the lowest practicable level.   | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification S-EG-02. EGI must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. EGD must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard S-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

They require proper operation to ensure gas does not exceed supply pressure. These sets consist of regulator(s), relief(s), riser, and meter. Failure of the regulation system has the potential to cause an over pressure to the customer's supply line and appliances. Over-pressure can result in a loss of containment within the building making the event of ignition, fire, and explosion possible. The condition of these Commercial/Industrial LPDMS is largely unknown. They have not been part of pro-active inspection programs. A survey on a sample population indicated a number of potential issues including: - Old Regulators - Corrosion of piping and regulators - Non-Adherence to installation specifications   | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

| Head Office/All | Div_54 - Head Office Support | Growth            | Pass                         |                      | 736972          | Hydrogen Fuel Heating Systems Feasibility Assessment        | 2025            | \$ 1,073,546                           | Issue/Concern/Opportunity: The feasibility study would explore two items:<br>1. Blending of hydrogen at gate and transmission regulating stations with the potential for on-site production of hydrogen. The study will quantify the maximum practical limits of hydrogen that can be blended into the natural gas fuel source of existing boiler systems.<br>2. Identifying the optimal site for a pilot project that will use an integrated pilot plant based on the availability of excess electricity and an opportunity to balance the demands on the electrical grid, availability of land for on-site hydrogen production and storage, and general operating conditions.<br><br>EGI will review 35 of its roughly 165 boiler facilities as part of its mainline Dawn-Parkway gas transmission system and associated downstream distribution stations. These stations regulate EGI's transmission gas pressures to lower distribution pressures to safely feed the Ontario natural gas distribution area. Due to the cooling of gas while regulating a high-pressure cut from transmission to lower distribution pressures, heat is required to mitigate the possible damage of the cooling effect to ensure safe and reliable operations for customers.<br><br>Additionally, the study will evaluate feasibility and alternatives for procurement or production of hydrogen as required to supply current boiler systems through Combined Heat & Power (CHP) applications where hydrogen will be used as the fuel source for boilers and the waste heat generated during hydrogen production is captured to maximize energy efficiency.<br><br>Assets: EGI will review 35 of its roughly 165 boiler facilities as part of its mainline Dawn-Parkway gas transmission system and associated downstream distribution stations<br><br>Related Program: 736973 - Hydrogen for Compression Facilities Feasibility Assessment | Completed                              | Fail                         | Hydrogen related projects are required as no IRPAs can replace the hydrogen feasibility assessments and hydrogen blending initiatives. | -                                     | -                           | -                                      | -               | -                  | -                           |

Associated 2024 Operations and Maintenance (O&M) spend for ILI.<br><br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30% Specified Minimum Yield Strength (SMYS). It includes installation costs for permanent ILI tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections. | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

Associated 2027 Operations and Maintenance (O&M) spend for ILI.<br><br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30% Specified Minimum Yield Strength (SMYS). It includes installation costs for permanent ILI tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections. | Completed                              | Fail                         | See investment description, IRPAs not applicable | -   | -                           | -                                      | -               | -                  | -                           |   |

Station 41902024 only requires SAP/field update (no project cost associated).  | In Progress                            |                              |  |                                       |                             |  |                 |                    |                             |
| Northern | Div_45 - Timmins             | Growth                | Pass                         |                      | 100936          | TIMM: West Timmins System Reinforcement (McBride North and Shirley/Riverside Stations) | 2025            | \$ 1,190,092                           | Issue/Concern/Opportunity: Based on generic subsystem growth, as defined by Network Analysis at 0.74% annually for Timmins, a project will be required around 2032 as pressures along Majestic Drive go below minimum. To resolve this capacity issue, either the HWY 101 bottleneck at Shirley/Riverside Drive can be resolved, or the McBride North DRS can be rebuilt to accommodate a higher outlet pressure.<br><br>However, the above conclusions/recommendations are based on the generic growth model. There is a relatively high probability that large commercial/industrial customers in the area of McBride North will be added to the system earlier than 2032, which would require that the above recommendations be acted upon as early as 2021. Depending on what loads are added, based on growth in this area of Timmins, Network Analysis will need to confirm at that time what the specific requirements are to accommodate the specific loads.<br><br>Distribution Optimization Engineering (DOE) identified this as a System Reinforcement Plan (SRP) project (FBPSTN_2018_41903048). If these modifications are not made, this could result in a denial of system attachments (i.e., forgone revenue). The worst case scenario is that there is no additional capacity, and/or there is an incident during the winter months causing outage.<br><br>Assets: Station ID 41903048<br><br>Related Program: This project might include modifications to the existing McBride North DRS (41903044), depending on the preferred solution to address the above issue/concern. | In Progress                            |                              |  |                                       |                             |  |                 |                    |                             |

| Southeast | 80 - Niagara         | Distribution Pipe | Fail                         | Dollar threshold     | 102425          | Relocation Program - Area 80*   | 2023            | \$ 13,084,164                           | <p>General Concerns: Vintage steel pipes exhibit increased failures as they age as steel mains are susceptible to external corrosion when barriers of pipe coatings and cathodic protection are compromised. The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (Vintage Steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization.</p> <p>Site-Specific Concerns: This project looks to replace approximately 8.7 km of mostly 1954 to 1960s vintage NPS 10 intermediate pressure (IP) pipe with sections of NPS 12 and NPS 8 spliced in over the years as repairs.</p> <p>A 2019 Depth of Cover (DOC) survey found that 366 (33%) survey locations had less than 90 cm of cover, and 90 survey locations (8%) had DOC&lt;60 cm, with one location found having exposed pipe due to creek erosion. Poor depth of cover leads to increased third-party damages (as has been seen with blow-off valves). Other risk factors include black coal tar pipe coatings used on 1959/1960 vintage NPS 10 pipe which show evidence of degradation, yielding to corrosion.</p> <p>There are many unusual fittings (Stop-and-Go) and unusual construction practices (such as using unrestrained compression couplings to tie in service connections) that can lead to difficult emergency responses. For example, a recent leak repair took 24 days to complete at a cost of almost \$500K due to complications from DOC, components, and construction practices. Unrestrained compression couplings (CC) have been the source of leaks due to ground settlement and increase the risk of pull-out. The river crossing at Twelve Mile Creek is very difficult to access due to steep creek banks and heavy vegetation, making it difficult to perform cathodic protection and leak surveys. It will pose as a significant concern for any required emergency response. The numerous transitions from NPS 8 to NPS 10 to NPS 12 also creates concern and difficulties for operational work to be completed.</p> <p>There are two main line valves that are suspected to be tied in with unrestrained CCs as per an Integrity Assessment for suspect CC locations. Cathodic protection for some of the NPS 10 segments has been historically poor, showing as much as 25% of historical readings over the last 20 years below minimum required levels.</p> <p>Assets: There is 8.7 km of mostly 1954 to 1960s vintage NPS 10 IP pipe with sections of NPS 12 and NPS 8 spliced in over the years as repairs that run along Glenridge Avenue from Russel Avenue south to Lockhart Drive, then along Lockhart Drive west to First Street South.</p> <p>Related Programs: Not applicable.</p> | In Progress                            | Technical Evaluation awaiting further integrity assessment to confirm project scope and timing. | -   | -                                     | -                           | -                                      | -               | -                  |                             |

Vintage plastic Aldyl A mains are the earliest plastic mains used within the distribution system; the installation period of Aldyl A plastics started in the late 1960s on a field trial basis and was concluded by the end of 1976 for the EGD rate zone and 1984 for the Union rate zones. It is well known and studied in the North American gas industry that Aldyl A plastic mains have brittle-like cracking properties. The oxidation of the inner wall surface during manufacturing (also known as Low Ductile Inner Wall (LDIW)) and the large spherulites found in its microstructure causes pipe to be susceptible to cracking and premature failure in the presence of stress intensifiers such as a large number of connections, squeeze-off locations, and the presence of rock impingement points caused by rocky soil types.  | Completed                              | Fail  | N/A - Project in construction phase   | -                                     | -                           | -                                      | -               | -                  | -                           |

| Southeast | 80 - Niagara         | Distribution Stations | Pass                         |                      | 3610            | CROWLAND STORAGE TRANSFER      | 2026            | \$ -                                   | Crowland Storage Transfer Station is located on EGI-owned property of approximately 7,300 m2 fenced compound in the Port Colborne, Ontario, approximately 7 km southeast of Welland, Ontario, within a rural area, in close proximity to a railway corridor. This station accepts natural gas from EGI Crowland Gas Storage facilities and provides supply to and from XHP networks, through components within the measurement system, pressure control system, heating system, odourant system, and telemetry system. This station delivers and withdraws natural gas from Storage Operations Wells in the Niagara Region. The following issues have been identified at this station:<br><br>Odourization: The odourant system was installed in 2000. The current configuration of the odourant system does not ensure adequate containment of the odourant product in the event of a leak and does not meet the current engineering standards and approvals.<br>Telemetry & Electrical: The existing electrical system does not meet current EGI electrical installation standards. This poses a potential electrical hazard and faulty wiring may result in lost communications.<br>Compliance: The Canadian Electrical Code Section 22.1 indicates that all electrical and instrumentation equipment located in a hazardous area must be rated for that area classification. The Remote Terminal Unit (RTU) building has been identified as being located in an area classification and its equipment is not rated to operate in this environment. This is a risk of ignition and fire in the event of a gas leak.<br><br>Scope Includes:<br>1) Install annubars on inlet and outlet.<br>-Install actuator on each operator regulator and on valves 8, 9 and 10.<br>Required electrical work:<br>-Relocate RTU building out of classified area (including new building and foundation).<br>-Install generator and automatic transfer switch.<br>-Upgrade tower to improve signal quality.<br>-Upgrade lighting.<br>2) Install filter separator and receiver on inlet.<br>-Install moisture analyzer and gas chromatograph.<br>-Install new Y2 odourant system (including new building and foundation).<br>-Include station bypass equipment and setup (assume bypass of the whole station is needed to complete the work). Includes retrofits to station piping for temporary station connection.<br>-Includes all planning/design costs including drafting, surveys and permits, and geotechnical study.  | Completed                              | Fail                         | N/A - Investment Cancelled  | -                                     | -                           | -                                      | -               | -                  | -                           |
| Southeast | 80 - Niagara         | Distribution Stations | Pass                         |                      | 3620            | MOUNTAIN RD GATE               | 2028            | \$ 4,772,735                           | Mountain Road Gate Station is located on EGI-owned property of approximately 1,800 m2 in a fenced compound in Niagara Falls, Ontario, approximately 10 km from Niagara Falls, within a rural/urban area. This station accepts natural gas from TC Energy and provides supply to one NPS 12 XHP network (Glendale), one NPS 12 HP network (Dorchester), and one NPS 8 IP network (Lundy's Lane). The gate station includes a measurement system, pressure control system, heating system, odourant system, and telemetry system. This station supplies natural gas to approximately 85,700 customers in the Niagara region. The following issues have been identified at this station:<br><br>Valves & Piping: Valve actuators have been installed on the outlet valves and on the heat exchanger isolation and bypass valves, but programming is required to control the actuators with the Remote Terminal Unit (RTU). Valves are functioning well but are all original valves that were installed during the installation of the gate station (approximately 30 years) and may need to be replaced due to age.<br><br>Measurement: The inlet is metered by a relatively new NPS 12 ultrasonic meter (approximately 10 years). The current system does not provide measurement of the individual outlet supplies. Visibility to each outlet supply provides greater redundancy to the existing measurement and improved response capabilities. Outlet metering is to be connected to SCADA and visible to the Gas Control group.<br><br>Heating: Three existing boilers at this site are old boilers that are approximately 20 years old. They have had 10 trouble call/failures over the recent years, including failures of the motors and pumps, burner lock-outs and exchanger failures. The existing heat exchanger was installed in 1995 and will be at end of life by the rebuild date. Due to recent and upcoming customer growth in the Niagara Falls area, the existing heating system will not be capable of supplying the heating requirements to meet the demand. Fuel gas station to the boilers is metered but conversion of the generator from diesel to natural gas will require it to be upsized.<br><br>Pressure Control: The configuration of the existing regulators are all boost-style regulators, posing an undesired higher risk and high associated ongoing maintenance costs. The regulators will have to be replaced. In addition, an upstream filter should be installed.<br><br>Odourization: The odourant injection system is a combination of Link and Wilroy pumps which are located in a separate building from the tank. The Pump building has no containment if a leak is experienced. The tank sits in a metallic odourant building without adequate containment which will have to be replaced with a functional building with proper containment, and ancillary equipment including fire suppression and gas detection. The current configuration of the odourant system does not meet the current engineering standards and approvals. The odourant package should be replaced. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

Issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGD develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long term plans EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. Enbridge reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers; and, - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Assets: Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth   | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |

The replacement program for meters is mandated by Measurement Canada. The program includes: testing, repair, and replacement requirements of meters and instruments. All verified meters are approved by Measurement Canada with an issuance of a certificate which identifies that the meter complies with Electricity and Gas Specification 5-EG-02. The Company must ensure all measurement devices remain in compliance for annual audits by Measurement Canada. Measurement Canada specifies tolerances under which the meter must operate in the field. The Company must demonstrate that all aspects of its meter sampling, maintenance, and replacement comply with these criteria in order to be accredited by Measurement Canada to be an "Authorized Service Provider" and adhere to Measurement Canada's accreditation standard S-A-01. Meters may also require exchange for issues such as: damages, leaks, customer billing issues. Regulation: Regulators are the last line of defense for over-pressure to the customer. The condition of regulation systems is determined by regulator performance, corrosion of piping and regulators, and adherence to installation specifications. Failure of the regulation system can cause pressurized gas to enter the premise, resulting in failure of gas equipment, loss of containment, and potentially fire or explosion.  | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

These mains are more susceptible to leaks as they have not been cathodically protected since installation. Removing these mains from service will reduce potential for leaks due to corrosion. If this project spend is reduced or deferred, more maintenance dollars will have to be spent repairing leaks on pipe which is nearing end of life.   | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

Scope of project would require a bypass of station to install the new inlet and outlet. There is a history of mercury in the soil in and around the Brantford Balmoral Gate Station, so soil assessments will be required. | On Hold                                |                              | Future year replacement projects are in the queue for IRP Evaluation and will be assessed annually when the scope is confirmed |                                       |                             |  |                 |                    |                             |

This will fall under the meter exchange budget and costs are not covered in this program. off the meter seal year is not between 2022 and 2026, the set will be rebuilt with a bypass the year after it is inspected. This will allow the technicians to identify which will require rebuilt at the time of inspection, and Sohan and I will be developing a process to get work orders generated for these rebuilds after the inspection. Also ensures that we focus our efforts on rebuilding active PFMs requiring rebuild. While I originally mentioned a proactive strategy to rebuild prior to the inspection year, we decided against that. -Assumption is that 50% of PFMs will need to be rebuilt. -Calculations are based on an estimate of \$5500 per rebuild. As you know there is a significant swing depending on the pipe size, volume, existing set up (first stage cut, etc) that may influence this including the release of the new SEADs designs, that I have not seen yet. | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

Constant bleeds on the control valves are causing the odour complaints. Consider Becker below grade ball valve station with no bleed pilots and DNGP for any needed flow control/pressure control. Fisher control valves are not a good option as they come with high O&M annual spend to operate and maintain.<br><br>VALVE & PIPING: Most valves becoming difficult to turn even with greasing. Many position indicators on tops of valves have fallen off due to ongoing corrosion.<br>FILTRATION: Filter decent shape – gas is dry and clean<br>HEATING: System is in constant state of repair and boiler age is old. A lot of corrosion on the glycol piping. There is not proper containment for the heat exchanger. Current system used all un-odourized gas inside.<br>PRESSURE CONTROL: Control valves needs support from Lakeside Controls to perform annual Operations<br>ODOURIZATION: Mois system (older vintage) room is very tight to get all assets inside the cabinet and room. Odourant cabinet in poor condition. No fire suppression system installed on odourant.<br>TELEMETRY & ELECTRICAL: Back up generator in decent shape. Electrical panels in poor shape and not properly labelled. All building do not have any methane detection or CO detection in boiler rooms.<br>MEASUREMENT - COMPLIANCE & OTHER Eng: Turbine meter is in decent shape and is used for process control only.<br>Buildings are old and in declining condition. One is brick facade and the others are metal buildings. Fencing in decent shape. Gates droop in the winter and would be better to go to the sliding gate standard. Consider adding swipe card access to compound and buildings to meet corporate security standards to compound and buildings. There is not a containment area for any chemicals being stored on site.<br>Ancaster Gate South is inside compound and is also in similar condition to Kirkwall-Dominion.<br>There is supposed to be a pig launcher added to this site.<br><br>Assets: 16W-606   | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| Southeast | Div_16 - Hamilton    | Distribution Stations | Pass                         |                      | 735048          | HAMI -CALEDONIA TRANSMISSION STN, Rebuild       | 2027            | \$ 7,998,768                           | Related Investments: N/A<br>Issue/Concern/Opportunity:<br>VALVE & PIPING: Most valves becoming difficult to turn even with greasing. Many position indicators on tops of valves have fallen off due to ongoing corrosion. Lots of corrosion on piping and leaks on an orifice meter that cannot be repaired. Frost heave on the Mount Hope line. Paint of piping in entire site is in poor condition and lots of external rust.<br>FILTRATION: Filter is getting replaced next month. If pigging at this site, a separator is needed.<br>HEATING: System is old and poor shape. The heaters are oversized and there is some cracking on some of the older boilers. Because heaters do not run the correct length of time, some of the gas lines remain frosted on the second and third cut. Heat exchangers are not contained and boiler rooms only have angle iron containment on the floors.<br>PRESSURE CONTROL: second station cut cannot keep up with demand to the Dunnville market. A pressure cuts are single regs and full capacity reliefs. Consider Becker buried ball valve station with no bleed pilots.<br>ODOURIZATION: no odourant on site<br>TELEMETRY & ELECTRICAL: Transmitters are old analogue devices and situated to make ongoing testing and maintaining difficult. Electrical panels are old and not properly labeled. There are no methane or CO detectors in boiler room. Should consider swipe card access to compound and buildings. Site does not have a back up generator.<br>MEASUREMENT - COMPLIANCE & OTHER Eng: Orifice measurement has leaks and should be upgraded to a properly sized turbine meter. Measurement runs do not have any bypass piping.<br>Site has an old storage building of metal construction. Need new storage building as this is a location where the Dunnville yard keeps materials and supplies in a remote location. There is not a contained area for any chemicals being stored on site. Need space from existing fencing to adjacent neighbors to keep vegetation controlled. Lots of vegetation coming up through fencing and gates are drooping, consider a new slide gate standard.<br>Site access is off of highway 6 where traffic is at a high rate of speed (80 kph +) Consider possibility of accessing yard from rear laneway. Front fence line should be lined with Jersey barriers for compound protection. Snow plowing is a challenge at this location due to closeness to road and high rate of traffic speed. Existing compound does not have any crash bar man gates for egress.<br><br>The heating system will be replaced during this project.<br><br>Assets: 15X-401<br><br>Related Investments: N/A | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (vintage steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization.  | On Hold                                |                              | Future year replacement projects are in the queue for IRP Evaluation and will be assessed annually when the scope is confirmed  |                                       |                             |  |                 |                    |                             |

The cost sharing for this work is managed through the Franchise Agreements established with municipalities. A consultative approach is used between the municipality and EGI to avoid conflicts with municipal infrastructure early in the planning stage. If a conflict is unavoidable, pipeline assets are typically relocated or replaced.  | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

This main is known to be very brittle, has a total of 4 known C leaks, and many lined services. A portion of this 4" PE main is lined in the former 6" S CT main installed in 1968 that continues on either side of Riverside Drive, making maintenance and new service connections extremely difficult. There are approximately 18 services renewals required. Main to be replaced with 1100 m of 4" PE IP.   | On Hold                                |                              | Future year replacement projects are in the queue for IRP Evaluation and will be assessed annually when the scope is confirmed  |                                       |                             |  |                 |                    |                             |

W. from Everts Ave. to Betts Ave. with 1,025 m of 8-inch S Yellow Jacket (YJ). This main is either too poor condition or laminated, and as a result cannot be welded on. In addition to weldability issues, several leaks have occurred over the last several years, which have all resulted in high capital expenditures to repair them. This main also requires many anodes try and maintain cathodic protection levels, all of which must be installed in wall-to-wall concrete. The most recent anodes were installed in the last two to three years meaning by 2025, new ones will need to be installed to replace them. This project will also include the renewal of 16 services.  | On Hold                                |                              | Future year replacement projects are in the queue for IRP Evaluation and will be assessed annually when the scope is confirmed  |                                       |                             |  |                 |                    |                             |

EGI promotes the use of natural gas to these customers as an alternate fuel source to provide a lower-cost and lower-emission fueling solution for vehicles such as garbage trucks, light duty vehicles, and transit buses. Business Development is responsible for the installation, maintenance, and the safe and continued operation of NGT stations assets for these customers. NGT stations differ in operation from distribution system stations as NGT stations use and store compressed natural gas (CNG) on site at up to 4000psi. EGD has two general categories for NGT station types: Large, Mobile and Utility NGT stations and Small NGT stations (also referred to as VRAs). Large, Mobile and Utility NGT stations are similar in operation and will be evaluated for condition in the same manner. Issue/Concern/Opportunity: Heater age (per integrity) is a concern.   | Completed                              | Fail                         | See investment description, IRPAs not applicable for CNG    | -                                     | -                           | -                                      | -               | -                  | -                           |

Frost heave occurs when the gas is cooled due to the pressure reduction and causes an upward swelling of soil around public or private property near the gas main. Freezing of station components such as creating large ice buildup around valves can prevent operation if gas isolation is required. This could result in the loss of pressure control and potentially lead to an overpressure or underpressure situation. The financial impact includes commodity loss, service disruptions, increased network leak surveys and system checks, repairs or replacement of company-owned property, or damages caused to public, commercial or industrial property. Inoperable systems will lead to a failure to maintain operational supply to customers.<br><br>Justification: Replace heater.<br><br>Assets: 130-402<br><br>Related Investments: Not applicable. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

| Southwest | Div_04 - London      | Distribution Pipe | Fail                         | Dollar threshold     | 48811           | LOND - Jacqueline BU - London                           | 2025            | \$ -                                   | Vintage steel pipes exhibit increased failures as they age as steel mains are susceptible to external corrosion when barriers of pipe coatings and cathodic protection are compromised. The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (vintage steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization. |  |                              |   |                                       |                             |  |                 |                    |                             |

The cost sharing for this work is managed through the Franchise Agreements established with municipalities. A consultative approach is used between the municipality and EGI to avoid conflicts with municipal infrastructure early in the planning stage. If a conflict is unavoidable, pipeline assets are typically relocated or replaced.  | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

These installations and replacements are based on the internal Standard Operating Practice established to maintain the appropriate level of cathodic protection on steel pipeline assets.  | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |
| Southwest | Div_04 - London      | Distribution Pipe     | Pass                         |                      | 100295          | Div_04: NPS 8 Port Stanley, London, Replacement        | 2026            | \$ 9,369,613                           | Issue/Concern/Opportunity:<br>The NPS 8 Port Stanley line is approximately 20 km of NPS 8 built in 1959, with unknown grade and wall thickness, bare and protected, and Dresser construction (some gas welded – such welds are usually susceptible to lack of fusion imperfections). There has been a history of a significant number of leaks due to corrosion on this single-feed system that provides natural gas to Port Stanley and St. Thomas, with about 13,000 customers including the St. Thomas hospital, a psychiatric hospital in St. Thomas and a retirement home in Port Stanley.<br><br>External corrosion has created difficulties with repairs due to the inability to weld. In one repair case, it took Operations three weeks to locate a suitable weld location for a repair. Repairs often require the use of split sleeves (\$8K/each). Depth of cover is a significant risk factor, with two exposed pipe sections being reported over creek crossings in December 2019. There are significant accessibility issues with locations of the pipe, making it difficult for emergency response and condition surveys. Some sections of pipe are heavily overgrown while other locations can be over 500 m from the nearest road. There are three below-grade stations that are considered confined spaces and which often flood, and must be evacuated before inspections and maintenance can occur. Gas supply from Lake Erie (New Dundee Comp) was known to have high moisture content and may contribute to internal corrosion.<br><br>No isolation is built into the single feed system; so if supply needs to be shut down, all downstream customers would be affected. In 2000, 6.8 km of main were replaced due to corrosion and exposed pipe. In 2003, 230 meters were replaced due to a Class B leak under a river crossing. Three casings on the system are known to be shorted. An attempted pressure increase in 1970 resulted in numerous leaks from compression couplings and pipe; therefore, the pipe cannot be pressure-elevated.<br><br>Assets: Port Stanley line is approximately 20 km of NPS 8 built in 1959.<br><br>Related Programs: Not applicable. | In Progress                            |                              | Technical Evaluation awaiting further integrity assessment to confirm project scope and timing.                                |                                       |                             |  |                 |                    |                             |

Associated 2024 Operations and Maintenance (O&M) spend for ILI.<br><br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30% Specified Minimum Yield Strength (SMYS). It includes installation costs for permanent ILI tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections.  | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

|           |                      |                       |                              |                      |                 |  |                 |  |  | Loss of Heating System Function: Loss of the heating system function could result in two scenarios, (1) frost heave or (2) pressure control failure due to the freezing of station components. Frost heave occurs when the gas is cooled due to the pressure reduction and causes an upward swelling of soil around public or private property near the gas main. Freezing of station components such as creating large ice buildup around valves can prevent operation if gas isolation is required. This could result in the loss of pressure control and potentially lead to an overpressure or underpressure situation. The financial impact includes commodity loss, service disruptions, increased network leak surveys and system checks, repairs or replacement of company-owned property, or damages caused to public, commercial or industrial property. Inoperable systems will lead to a failure to maintain operational supply to customers.  |                              |                               |   |                             |  |                 |                    |                             |   |

Associated 2026 Operations and Maintenance (O&M) spend for ILI.<br><br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30% Specified Minimum Yield Strength (SMYS). It includes installation costs for permanent ILI tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

Industry benchmarks suggest that reciprocating engine block foundations degrade in 25 years or less for engines that run 24/7. Excessive bearing deflections place cyclic stresses on the crankshaft of the unit, leading to increased frequency of bearing failure and increased potential for a crankshaft fatigue failure. Unit reliability will be diminished dramatically if repairs are not performed. Worst case consequence is unit unavailability during a design day. Compressor foundations have been considered in the Asset Health Review. Condition assessment is largely visual. The telltale sign of poor foundation condition is the existence of cracks on the surface of the foundation, with oil seeping out of the crack. Cracks typically extend to a depth that is consistent with the bottom of the unit's anchor bolts. Without remediation, failing foundations will allow unit settlement, creating a misalignment of bearings. Frequency of bearing failures increases reducing operation reliability. Collateral damage to the crankshaft is also common.<br><br>Asset: Compressor foundations<br><br>Related Programs: Not applicable | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. | STO - EGD | 70 - Storage         | Transmission Pipe & Underground Storage | Pass                         |                      | 13044           | PSEC:TS22H Well-Install               | 2024            | \$                                     | - Issue/Concern: Micro-annulus leaks have been occurring on wells that have been relined. Relining a well may be performed when the integrity of an existing casing is inadequate, and a smaller diameter casing is installed inside the original casing (concentrically). A recent rash of these relined wells has experienced leakage between the two casings.<br><br>Concerns:<br>1.Localized leakage can be prevented by sealing the flow path at the wellhead (casing vent). This action causes pressure in the space between the two casings to achieve full reservoir pressure.<br>2.If the annulus space is allowed to be pressurized, there is the potential for a breach of the original casing; the original casings are known to have inadequate integrity.<br>3.A breach of the original casing could occur anywhere along the well string which is 2,000 ft long/deep. Leaking, undissolved gas could come to surface at unpredictable locations. About half of the relined wells operated by EGI are those which have not yet started to leak. Of the 20+ relined wells currently in-service at EGO Storage, 11 were recently found to be actively leaking and are being or have been abandoned. The mechanism by which a relined well becomes a leaking well has not been conclusively determined. The remaining (non-leaking) wells are expected to develop a leak in the short term. Once the wells are actively leaking, the problem becomes a compliance issue as follows:<br><br>•CSA 2341.1-14 - 5.3.1 (a) The design of a well casing program shall provide control of pressures and fluids encountered by the well.<br>•CSA 2341.1-14 - 5.3.6 (c) Well casings shall be set and cemented at sufficient depth to ensure isolation of storage zones.<br>•OGSRA (O/Reg 245.97) - 17 (1) An operator of a well...shall provide casing and blowout prevention equipment and maintain it in such a condition that any oil, gas or water encountered can be effectively controlled.<br>•OGSRA (O/Reg 245.97) - 17 (3) The operator shall ensure that the well does not flow uncontrolled.<br>•O. Reg. 22/00, s. 6 (2) Well abandonments resulting from the Leaking and Relined well replacement programs will diminish the flow capacity of the associated reservoir. This performance degradation negatively impacts peak day deliverability. Reservoir performance deterioration, due to abandonment of relined wells, is currently unknown.<br><br>Assets: Seckerton reservoir (Wells and Well Equipment asset program) and gathering system (Field Lines asset program).<br><br>Related Programs: Installation of wells is performed by the reservoir group (Wells and Well Equipment asset program), installation of laterals is performed by the project execution group (Field Lines asset program). This separation is based on skill set and qualifications. There is a programmatic time dependence between the two asset programs. | Completed                              | Fail                         | Storage Pools & Well related projects are required to maintain existing deliverability and throughput. This is necessary to maintain security of supply and stable natural gas pricing during supply disruptions. | -                                     | -                           | -                                      | -               | -                  | -                           |
| STO - EGD | 70 - Storage         | Transmission Pipe & Underground Storage | Pass                         |                      | 13047           | PSEC:TS23H Well-Install               | 2024            | \$                                     | - Issue/Concern: Well abandonments resulting from abandoned wells since 2007 have already diminished the flow capacity of Seckerton. The proposed relined well replacement program will diminish the flow capacity of the Seckerton Reservoir even further. In addition, wells on the northern saddle of Seckerton (referred to as Seckerton North) are being shut in during low-end withdrawal in order to mitigate crude oil carryover. The North and South saddles have limited interconnected permeability, meaning that gas migrates very slowly between the two saddles. Shutting in wells has the effect of stranding an estimated 1.5 BCF for three weeks at the end of the withdrawal cycle. This performance problem negatively impacts peak day deliverability.<br><br>Assets: Seckerton reservoir (Wells and Well Equipment asset program) and gathering system (Field Lines asset program).<br><br>Related Programs: Installation of wells is performed by the Reservoir group (Wells and Well Equipment asset program), installation of laterals is performed by the project execution group (Field Lines asset program). | STO - EGD | 70 - Storage                 | Transmission Pipe & Underground Storage | Pass                         |                      | 735770          | A1 observation program*                                     | 2022            | \$ 4,776,008                           | Issue/Concern: Observation wells are required pursuant to Section 7.5 of CSA 2341 – Storage of hydrocarbons in underground formations . The observation well will monitor gas content and pressure in the underground storage area which will assist with the continued safe and reliable delivery of natural gas to our existing and future customers. Section 7.5: "Observation wells shall be incorporated into the storage facility and shall monitor pressures and the presence of hydrocarbons within the storage zone and associated permeable zones. The location and design of the observation well shall take into consideration: (a) locations within the storage zone that are suitable for monitoring reservoir pressures; (b) potential migratory paths from the reservoir to another formation; (c) fluid interface monitoring at the location of the spill point; (d) permeable zones and stratigraphic traps above the storage zone; and (e) low-permeability zones or formations adjacent to and in communication with" In addition, interpretations of the latest reservoir simulations indicate that the A-1 sucrosic dolomite may extend beyond the geographical edge of some DSAs. The DSA boundary protects the reef from any unwanted drilling by a third party. If the A-1 does, in fact, extend beyond the DSA boundary, a third party could receive permission to drill and if they penetrated the A-1 sucrosic they would be connected to the associated reef. EGD would then be forced to extend the DSA boundary and include, or buy out, the 3rd party. While the seismic provides a good interpretation of the A-1 it is not definitive and the only way to fully determine if the A-1 sucrosic is located beyond the boundary of the DSA is to drill a well. Mitigation of this risk will protect EGD's rights to the associated reservoir facility. Finally, the A1 Observation wells were originally proposed as a means to verify the integrity of the reservoir boundaries and demonstrate the relationship of low permeability zones to LUF. EGD receives rate recovery on LUF, and A1 zones were considered a potential means by which gas was leaking out of the reservoirs or becoming trapped, thereby creating LUF. The issue is that EGI must continue to investigate causes of LUF in order to argue for cost recovery from rates.<br><br>This program drills one A1 well per year for 9 years.<br><br>There are currently no A1 observation wells at the following pools.<br>Airport<br>Oil Springs East<br>Mandaumin<br>Oil City<br>Bluewater<br>Heritage<br>Tipperary<br>Black Creek<br>Chatham D<br>Wilkesport | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

| STO - UG | Div_53 - Union South Storage | Compression Stations | Pass                         |                      | 48231           | Parkway A Gas Generator(38148) End-of-Life Overhaul | 2027            | \$ 2,772,906                           | Issue/Concern/Opportunity: The consequence of compressor failure is dominated by gas cost impacts to customers. The compressor package is comprised of a gas turbine engine driver, compressor, power turbine and ancillary equipment such as lube oil, fuel supply, and electronic control systems, which are required for the compressor to operate. The gas turbine engine is very complex and carries the greatest failure risk of all of the compressor package components. By continuing to comply with original equipment manufacturer (OEM) recommended Preventive Maintenance (PM) schedules and overhauls, compressor reliability risks are controlled to moderate levels. In the case of performing regular OEM prescribed overhauls, the risk of unit failure is proposed as a sawtooth function, whereby risk increases gradually over the recommended interval between overhauls and then drops suddenly after an overhaul. Critical internal wear components are on a path to failure and generally in sync with operating hours. If the operating hours are extended too far, the resulting additional operational stress on internal components, such as high temperature coatings and bearings, will increase the component scrap rate when performing the overhaul. This will add significant (10 to 20% or more) cost to the base overhaul and increases the risk of a random failure leading to system unreliability and further cost increases.<br><br>Justification: Potential for unexpected or catastrophic failure if timing is extended.<br><br>Assets: Avon serial 38148<br><br>Related Investments: Not applicable. | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. These activities will support additional detailed alternatives analysis and final scoping which will in turn inform the project cost estimate, timing and business case.</p> <p>Dawn C Plant is one of the nine centrifugal compressors located at the Dawn Compressor Station. It is primarily used to lift from lower storage pressure levels, experienced later in the operations season, to intermediate pressure levels. The intermediate pressure level is typically elevated further in pressure by another compressor to reach the desired Dawn outlet pressure. Dawn Plant C and Plant D have a suction pressure rating of 195 psig, the lowest rating of the compressor fleet at Dawn. Considering the other compressors at Dawn have a 225 psig minimum inlet rating, Dawn Plants C and D become very critical when pool storage levels fall below 225 psig, as they typically do late in the operational season. Overall, compression can pose a very large consequence of failure as compressors are integral assets required to achieve the Dawn to Parkway Transmission System deliverability requirements throughout the year.</p> <p>The consequence of compressor failure is dominated by gas cost impacts to customers. Transmission system consequences associated with failure of a single compressor are heavily influenced by the time of year, weather severity and time to mitigate the failure. Siemens, the original equipment manufacturer (OEM) of the Dawn C compressor, has indicated that 40 years is the typical timeframe for supporting the supply of engine parts required to recover from a critical engine failure or to complete recommended overhauls. Dawn Plant C was installed in 1984, which indicates that the RB211- 24A engine in Plant C is reaching end of life.</p> <p>Justification: By continuing to comply with OEM-recommended Preventive Maintenance (PM) schedules and overhauls, compressor reliability risk is controlled to moderate levels but risk increases gradually over the 25,000-hour recommended interval between overhauls. Availability of parts is essential to repair internal engine failures and complete overhauls. Notably, the RB211-24A in Plant C has non-standard dimensions and cannot be retrofitted with more modern editions of the RB211 without significant plant retrofits. Similar to the 40-year old Dawn Plant B, which was replaced and retired in 2017 due to the risks associated with discontinued OEM support of critical engine parts, it is expected that Dawn Plant C will be exposed to a similar level of risk as the global inventory of spare components diminishes.</p> <p>Assets: Dawn Plant C</p> <p>Related Programs: Not applicable.</p> | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. These activities will support additional detailed alternatives analysis and final scoping which will in turn inform the project cost estimate, timing and business case.</p> <p>The Waubuno compressor elevates available pipeline pressure to the Waubuno Pool Maximum Operating Pressure (MOP). Compression increases the working inventory value of the pool by approximately3.5 PJ on top of what the pipeline alone can achieve. The compressor is operated approximately 45 days per year in late summer to early fall to top off the pool. The consequence of compressor failure is dominated by customer impact. Risk associated with failure of the Waubuno compressor is heavily influenced by the level of the pool at which the failure occurs and time to mitigate the failure.</p> <p>The Joy Compressor (manufactured in 1985) was a used compressor package and installed at Waubuno in 1988. The Joy Compressor Company changed ownership approximately 20 years ago whereupon original equipment manufacturer (OEM) support for the compressor was discontinued. Although normal wear components are still available in the marketplace, replacement major compressor items such as cylinders, crankshafts, and rods, etc., required to support a critical failure are no longer available. In the event of a critical failure, sourcing used parts (which are rare) or aftermarket custom machining services would be the only options for repair. This was the case in 2007 when a discharge valve seat failed, resulting in catastrophic damage to cylinder 611. An extensive search across the used parts dealers was required to secure a viable used cylinder head. Other internal damage was repaired through custom machining services.</p> <p>Justification: In the event of a future failure, if usable parts or custom machining are not available, the two options would be custom-designed aftermarket castings (if possible) or replacement of the entire compressor. However, both options would render the compressor out of service for at least one operational season.</p> <p>Assets: Waubuno Compressor</p> <p>Related Programs: N/A</p>  | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. The compressor package is comprised of a gas turbine engine driver, compressor, power turbine and ancillary equipment such as lube oil, fuel supply, and electronic control systems, which are required for the compressor to operate. The gas turbine engine is very complex and carries the greatest failure risk of all of the compressor package components. By continuing to comply with original equipment manufacturer (OEM) recommended Preventive Maintenance (PM) schedules and overhauls, compressor reliability risks are controlled to moderate levels. In the case of performing regular OEM prescribed overhauls, the risk of unit failure is proposed as a sawtooth function, whereby risk increases gradually over the recommended interval between overhauls and then drops suddenly after an overhaul. Critical internal wear components are on a path to failure and generally in sync with operating hours. If the operating hours are extended too far, the resulting additional operational stress on internal components, such as high temperature coatings and bearings, will increase the component scrap rate when performing the overhaul. This will add significant (10 to 20% or more) cost to the base overhaul and increases the risk of a random failure leading to system unreliability and further cost increases.</p> <p>Assets:</p> <p>Related Investments:</p>   | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. Flow dynamic of natural gas out of this critical supply high deliverability pool into the Dawn Yard has changed over the years such that the flow regime during normal non-peak day operations falls greater than the capability of the low-flow control valve run but at the very low end of the large control valve flow run. The high-flow control valve is an older style ball Fisher type valve which does not work efficiently at low flows. Extreme noise is created, over the 100 dB level, resulting in high cycle vibration of the valve internals leading to premature failure. A failure occurred in 2019 whereupon a clanging noise was being produced. The valves were removed and examined by Fisher. The large diameter valve was found to be excessively worn. Fisher rebuilt the large diameter valve after which it was reinstalled in order to place the 5985 pool back in service. Fisher's recommendation is that EGI avoids operating the large diameter valve under these conditions.</p> <p>Assets: Control valves (CV 12 and CV 20)</p> <p>Related Investments: Not applicable.</p>  | Completed                              | Fail                         | Compression Station related projects are required to maintain existing deliverability and throughput. While this is not currently mandated by code in Canada, it is required in the U.S. and is expected to become a requirement in Canada in the future. Given the number of pipelines greater than 30 per cent SMYS, MOP Verification will be a multi-year project requiring a dedicated team to complete the verifications and determine if any pipeline remediation is required. This forecast includes the costs of replacing sections of pipelines as identified through the MOP verification work. MOP verification was also included in the 2017 customer engagement survey; while 43 per cent of those surveyed recommend waiting for regulation requirements to keep costs down, 40 per cent recommend proactively implementing industry standard. Spreading the verifications over several years will keep costs down and proactively implement an industry standard, which provides additional support for this program. Starting this program as forecast will mitigate the need for higher expenditures in a shorter time frame to meet these expected future mandated requirements. | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

While this is not currently mandated by code in Canada, it is required in the U.S. and is expected to become a requirement in Canada in the future. Given the number of pipelines greater than 30 per cent SMYS, MOP Verification will be a multi-year project requiring a dedicated team to complete the verifications and determine if any pipeline remediation is required. This forecast includes the costs of replacing sections of pipelines as identified through the MOP verification work. MOP verification was also included in the 2017 customer engagement survey; while 43 per cent of those surveyed recommend waiting for regulation requirements to keep costs down, 40 per cent recommend proactively implementing industry standard. Spreading the verifications over several years will keep costs down and proactively implement an industry standard, which provides additional support for this program. Starting this program as forecast will mitigate the need for higher expenditures in a shorter time frame to meet these expected future mandated requirements. | Completed                              | Fail                         | See investment description, IRPAs not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |

The well UI20 is in a flood plain which is inaccessible during the spring months. Any response to a well incident would be severely impacted by the condition of the well and access to the well. The proposed abandonment of this will reduce deliverability. This project drills abandoned one well UI20 and drills two 8 5/8-inch wells. The two new wells will offset the reduction of deliverability due to the relines and abandonments. Assets: Waubuno pool and Gathering lines Related Program: Not applicable.  | Completed                              | Fail                         | Storage Pools & Well related projects are required to maintain existing deliverability and throughput. This is necessary to maintain security of supply and stable natural gas pricing during supply disruptions. | -                                     | -                           | -                                      | -               | -                  | -                           |

The BOG compressor was also used to recover BOG (i.e., natural gas vapours) from the liquefied natural gas (LNG) storage tank which occurs on a continuous basis due to the ambient warming of the tank exterior. In 2012, a separate compressor was installed to manage the LNG storage tank boil-off gas.<br><br>The BOG compressor is necessary to produce LNG. The consequence of compressor failure is dominated by customer impact. Risk associated with failure of the BOG compressor is heavily influenced by the time of year, weather severity and time to mitigate the failure. Over its 50 years of operation, the 240 horsepower Ingersoll Rand BOG compressor has amassed 325,000 operational hours. The compressor is obsolete and, although normal wear components are still available in the marketplace, some core compressor replacement parts such as cylinders, crankshafts, pistons, etc., required to support a critical failure may no longer manufactured by the original equipment manufacturer(OEM). In the event of a critical failure, securing used parts (which are rare) or aftermarket custom machining services are the only options for a timely repair. This was the case in 2017 when an aftermarket service was solicited to develop a weld and machine repair of a compressor cylinder which had failed. The aftermarket service was able to design a custom repair which took three months to complete. In the event that the cylinder is not repairable, a custom-designed aftermarket casting or a complete replacement of the compressor may be options. These options would take the plant out of service for at least one operational season.<br><br>Assets: BOG compressor<br><br>Related Programs: Not applicable | Completed | Fail                                   | See investment description, IRPAs not applicable | -                             | -                            | -                  | -                             | -               | -                  |                             |

| Toronto | 10 - Toronto         | Distribution Pipe | Pass                         |                      | 4160            | Vintage Steel: NPS 12 SC HP on Parliament St, Carlton St to Front St | 2025            | \$ 2,826,373                           | Issue/Concern:<br><br>General Concerns: Vintage steel mains have shown signs of declining health due to the cumulative effect of poorly manufactured coating performance, construction practices, latent third-party damages to pipe coating, and the effect of stray currents from transit infrastructure such as subway and streetcars. The current failure projection model is forecasting an exponential increase in the number of corrosion-related failures, while the quantitative risk assessment and the 40-year risk projection are showing an increase in the safety risk associated with steel main failures. In addition to its age, vintage steel mains are also susceptible to accelerated degradation and/or higher risk of third-party damage in the following ways:<br>1)Compression couplings (e.g., mechanical fittings which are not welded onto the main) on steel mains that are not properly restrained or unrestrained could cause a loss of containment due to exposed points of thrust. In this case, the weight of the soil is required to hold the fittings in place. When the soil is disturbed, the pipe pulls out of the fitting, resulting in blowing gas through the open pipe end with the potential of full bore release of gas.<br>2)Compression couplings on steel mains that are unknowingly isolated from the corrosion protection system could result in inadequate cathodic protection, leading to the assets' accelerated corrosion and potentially loss of containment.<br>3)The existence of shallow blow-off valve assemblies could be damaged during excavation activities.<br>4)Reduction in the original depth of cover due to urban development could increase the potential of damages due to excavation activities and increased external loading. According to the codes and standards, a minimum depth of cover is needed to ensure the appropriate distribution of weight of transportation vehicles across pipelines is not exceeded. If the depth of cover is not appropriate, excessive stresses are introduced into the pipe and failures could result.<br>5)The continuous exposure of road salt and seasonal ground movement on bridge-crossing assets could result in accelerated corrosion and external loading/stresses.<br>6)Lack of cathodic protection with pipe casings could result in corrosion causing excessive stress or shorts on the carrier pipe that is in contact with the casing, which could lead to the loss of containment.<br>7)Manufacturing defects associated with seam welds and fittings that are weak points in the distribution system could result in a loss of containment due to prolonged exposure to stress and corrosion.<br>8)Latent damages to pipe coatings that were never reported to EGI for repair and became active corrosion sites could hamper the effect of the corrosion protection system and result in accelerated corrosion and potentially loss of containment.<br><br>Site-Specific Concerns: Early 1960s NPS 12 SC High Pressure (HP) subject to corrosion issues should be replaced. Coating damages and corrosion leaks were previously reported on the northern section of this NPS 12 gas main, which was replaced in 2015. Replacement pipe size is to be finalized by Planning during design phase.<br><br>Assets: Network 180 KOL system.   | Completed                              | Fail                         | Timing - Market based supply side alternatives not applicable                                   | -                                     | -                           | -                                      | -               | -                  | -                           |

The current failure projection model forecasts an exponential increase in the number of corrosion-related failures. In addition to age, vintage steel mains are also susceptible to accelerated degradation and/or higher risk of third-party damage in the following ways:<br>- Compression couplings, Shallow blow-off valve assemblies that could be damaged during excavation activities, Reduction in the original depth of cover, Continuous exposure to road salt and seasonal ground movement on bridge crossing assets, Lack of cathodic protection on pipe casings that could result in corrosion and lead to the loss of containment, Manufacturing defects on seam welds and fittings that could result in leaks due to prolonged stress and corrosion and Latent damages to pipe coatings that were never reported to EGI for repair and became active corrosion sites, resulting in accelerated corrosion and potentially loss of containment<br><br>Site-specific Concerns:<br>The NPS 20 Lake Shore Replacement project from Cherry Street to Bathurst Street addresses vintage steel mains installed in 1954. This project was assessed using Asset Health Review methodology, the C5S value framework, tacit knowledge from internal stakeholders and in-line inspection (ILI)/Integrity dig results. In addition to the declining health demonstrated by vintage steel mains, this pipeline is part of the KOL system in the Toronto area, known to have a number of features that make it more susceptible to accelerated degradation and/or higher risk of third-party damage. These features include but are not limited to:<br>- Compression couplings on mains and services, Reduced depth of cover, Shallow blow-off valves, Lack of cathodic protection, Live stubs, Stray current from hydro infrastructure , Possibly contaminated soils<br><br>In 2016 and 2018, inline inspections (ILI) using a robotic crawler were performed on approximately 1.9 kilometres of the 4.5 kilometres of pipe selected for Phase 1. The 2016 ILI survey found 2 areas that required immediate rehabilitation activities via 2 Integrity digs. There are an additional six integrity digs recommended over the next 10 years. The 2018 inspection identified 24 further dig locations that would require Integrity remediation over the next 10 years as per the guidance from CSA Z662. These digs are required to mitigate the corrosion and dent features that could exhibit more than 80% wall loss or have a high probability of failure, representing significant degradation of the pipe. Costs for such integrity digs, based on the integrity digs in 2017 and 2018, range from \$350,000 to \$450,000 per integrity dig. This implies that over the next 10 years EGI could be expected to spend \$10,500,000 to \$13,500,000 to rehabilitate these 30 locations, leaving the remaining pipe as bad as old. These Integrity digs would also require multiple construction zone impacts to the local traffic and businesses in a highly congested area of downtown Toronto. The multiple interruptions would have a negative impact to the reputation of safe and reliable service for EGI. Furthermore, the ILI survey also indicated another 10 features that may require mitigation activity within 15 years (\$3.5M-\$4.5M additional spend), which is an indication that the pipe is reaching the end of its safe and reliable service life and that a repair approach is not a sustainable approach. | Completed                              | Fail                         | N/A - Project in construction phase   | -                                     | -                           | -                                      | -               | -                  | -                           |
| Toronto | 10 - Toronto         | Distribution Pipe | Pass                         |                      | 11443           | NPS 12 Martin Grove Rd Main Replacement: Lavington to St. Albans Rd. | 2026            | \$ 4,537,312                           | Issue/Concern:<br><br>General Concerns: Vintage steel mains have shown signs of declining health due to the cumulative effects of poorly manufactured coatings, construction practices, latent third-party damages to pipe coatings, and the effect of stray currents from transit infrastructure (such as the subway and streetcars). The current failure projection model forecasts an exponential increase in the number of corrosion-related failures. The C5S value framework and the 40-year risk projection show an aggressive increase in the safety risk associated with steel main failures. In addition to age, vintage steel mains are also susceptible to accelerated degradation and/or higher risk of third-party damage in the following ways:<br>•Compression couplings<br>•Shallow blow-off valve assemblies that could be damaged during excavation activities<br>•Reduction in the original depth of cover<br>•Continuous exposure to road salt and seasonal ground movement on bridge-crossing assets<br>•Lack of cathodic protection on pipe casings that could result in corrosion and could lead to the loss of containment<br>•Manufacturing defects associated with seam welds and fittings that could result in a loss of containment due to prolonged stress and corrosion<br>•Latent damages to pipe coatings that were never reported to EGI for repair and became active corrosion sites, resulting in accelerated corrosion and potential loss of containment.<br><br>Site-Specific Concerns: Martin Grove to St. Albans Road: Address NPS 12 pipe from Lavington Drive South to Burnhamthorpe Road, then west to Ashbourne Drive, then following Auckland Road south to St. Albans Road.<br><br>There are over 360 service connections that will be removed from the high-pressure (HP) steel main and an intermediate pressure (IP) polyethylene (PE) subsystem installed to reconnect these customers. Depth of cover (DOC) has been identified as a significant concern for these main segments as identified by 2018 and 2019 DOC surveys that found over 52% of the survey locations had DOC less than 90 cm, with 77 survey locations measuring less than 60 cm of cover. Poor DOC can lead to increased third-party damages. Additional risk factors include two unrestrained compression couplings (CCs), nine restrained CCs, and three suspect valves where, due to their installation dates, may have been tied in using unrestrained CCs (as discovered by an Integrity Assessment showing significant correlation between valves of this vintage with unrestrained CC tie-ins).<br><br>Cathodic protection history for the past 20 years shows that over 15% of the readings taken each year were below the minimum requirements. Poor cathodic protection levels can lead to corrosion.<br><br>Assets: NPS 12 pipe from Lavington Drive south to Burnhamthorpe Road, then west to Ashbourne Drive, then following Auckland Rd. | Toronto | 10 - Toronto         | Distribution Pipe | Pass                         |                      | 13612           | Service Relay Blanket - Area 10*                                     | 2023            | \$ 114,922,014                         | General: A distribution service refers to the pipe between the distribution main and the customer's meter set. Over the years, different materials have been used for this asset, including steel, copper, and varying resins of plastic, each with unique characteristics that contribute to their performance over time. Services can be repaired or replaced depending on asset condition and the nature of the issue exhibited. Generally, replacement is the preferred approach to mitigate unacceptable asset condition.<br>Issue/Concern: Currently, a 2-inch SC HP gas line (asset 61054) is sole feed to Toronto Island and is running through Western Gap Utility Tunnel. The utility tunnel is now considered a mine shaft, preventing necessary inspections of the line and the hangers that are supporting the line. This 2-inch SC HP main was installed in 1963 and the last known inspection of this line and hangers was in 1992. Should the line fail, the only recourse would be shutting the feed to Toronto Island, losing approximately 300 customers and undertaking an emergency replacement to resume service.  | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (vintage steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization.<br><br>Assets: Approximately 1623.3 m 2-inch SC Intermediate Pressure (IP) to be replaced by 2-inch PE IP.<br><br>Related Investments: Investment code #735792.   | Completed                              | Fail                         | NPS 2, cannot downsize or retire   | -                                     | -                           | -                                      | -               | -                  | -                           |

This will allow in-line inspection of the pipeline which is required as per the Pipeline Integrity Management Program.<br>General: The Integrity Management Program is a mandated regulatory requirement which has been designed to comply with all applicable codes and standards. The program consists of the regular assessment and maintenance of the integrity of EGI's pipeline systems to ensure their continued safety and reliability. Most of the expenditure included in this category is for pipelines that operate above 30 per cent SMYS. It includes installation costs for permanent inline inspection (ILI) tool launcher and receiver facilities, retrofits to existing lines to remove restrictive fittings or pipe configurations so they can be inspected with ILI tools, and replacement of pipeline segments with integrity issues that are identified through the inspections. | Completed                              | Fail                         | See investment description, IRPAs not applicable   | -                                     | -                           | -                                      | -               | -                  | -                           |

The current pipe replacement rate (mains and services) is inadequate to prevent the average age of the population from increasing and hence reaching the end of their useful life. EGI has determined that a long-term proactive replacement program targeting higher-risk steel pipes installed on or before 1970 (vintage steel) is required to manage the increasing number of expected leaks that create increasing risk for the organization.<br><br>Comments: There is potential for road restrictions due to congested area.<br><br>TOR10YR - Westhead Replacement - Network #123_368_373<br><br>Medium Pressure (MP) system is running close to capacity and not meeting growth needs. | Toronto | 10 - Toronto         | Distribution Stations | Pass                         |                      | 3605            | BAYVIEW FEEDER  | 2024            | \$                           | 7,705,923 | Pipe, Valves & Others: Updated piping is required for this station to connect the new valve's and fittings and other associated materials. New inlet (NPS 12) and outlet (NPS 16) piping configurations are required to separate Maximum Operating Pressures (MOPs). Bayview Station will need to be shut in to execute piping installation. Station inlet filtration (gas separator) will be considered during the rebuild.  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Heating System: Updated heating is required at this station. Due to the area, this would more than likely be a conventional boiler system with two boilers minimum for heating load and redundancy. New building (concrete is required) with Glycol piping and new Glycol substance is required. The building is to be outfitted with all electrical elements (-5°C outlet temps during winter). A new heat exchanger will be required.   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Pressure Control: New regulation is required to support pressure cuts to separate MOPs. Three new runs (Operator and Monitor) will be required. These will be Becker Control Regulators and six are required.   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Odourant System: Not required.  |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Telemetry/Electrical: Telemetry assets have been deemed within the hazardous classified area. Relocation of assets is required. New Control Wave Micro unit and associated connections are required. A new generator is required to support backup power requirements. Pressure and temperature transmitters (two each) are required.   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Measurement: The orifice plate is improperly sized and not accessible (below grade) and is to be replaced with above grade including piping. New Annubar on outlet of station is required for redundant measurement.  |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Building: A new, large building format is required. The boiler, regulator and Remoter Terminal Unit (RTU) are all to be under one building (similar to Station A approach).   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Compliance/Civil: Site grading and new security fencing (galvanized) including new swing gate and crash bar access will be required. Existing lands will need to be confirmed if property is owned or leased. Tree trimming/removal may be required. The station is located on the Don Valley Trail.  |  |                              |   |                                       |                             |  |                 |                    |                             |
| Toronto | 10 - Toronto         | Distribution Stations | Pass                         |                      | 17403           | NGT Existing customer Maintenance Capital - (+2027)*          | 2028            | \$                           | 2,771,364 | Issue/concern: EGI Fleet operators can continue to achieve fuel cost savings and reduced emission benefits by investing in the wellbeing of the NGV station. This can be achieved by adopting continuously upgrading the major NGV equipment as part of the maintenance strategy. By upgrading the major NGV equipment, EGD can extend the life cycle of the equipment, resulting in a more cost effective way of operating the NGV stations. Assets: There is a number of current NGV Station EGI maintains.   | Completed                              | Fail                         | See investment description, IRPAs not applicable for CNG    | -                                     | -                           | -                                      | -               | -                  | -                           |

| Toronto | 10 - Toronto         | Distribution Stations | Pass                         |                      | 503183          | Albion Feeder Station Control Valve Upgrade                   | 2024            | \$                           | 644,855   | At Albion Gate, valve F54201D controls the flow rate from the EGT line to the TC Energy Kings North outlet. All gas flowing to TC Energy must pass through the valve; there is no bypass, isolation, or redundancy included in the existing design. If this valve (F54201D) failed (and required maintenance), the inlet to both the EGI system and TC Energy's outlets would be affected. The original purpose of the valve was to control flow to TC Energy to their contractual limit when flows on the EGT line were at their peaks. This control would guarantee the inlet pressure to the station feeding the EGI XHP systems which would be sufficient during peak operations. | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | It was expected that this valve would be primarily 100% open and only be in service on the coldest of high-market demand days. Utilization was expected to be less than 10% of the winter days. In the winter period November 1, 2020 to February 25, 2021, the valve had been less than 100% open, 50% of the time (1407 hours / 2788 hours – source SCADA). Gas Control has utilized this valve more often for two purposes: (1) to carry higher pressure to Albion Gate for the distribution station; and (2) to maintain the operation of Parkway West compression within tolerances.   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Parkway West compressors are each 40,000 HP plus units. For the units to operate in their limited emission mode, both the volume pumped by the compressor and the lift across the compressor must be maintained within specific ranges. Using F54201D at Albion to limit flow to TC Energy allows the EGT line to act as a buffer for the compression. Compression volumes and lift can be maintained by operating the EGT line at higher pressure on warmer days.  |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Risks: With no bypass and a single valve, a failure of the valve to open when needed will not allow EGI to deliver contracted quantities to TC Energy. Although this station rarely operates in summer months, summer would be the only time to work on the valve controls.   |  |                              |   |                                       |                             |  |                 |                    |                             |
|         |                      |                       |                              |                      |                 |   |                 |                              |           | Recommendation: Identify the appropriate design for the control valve feeding TC Energy Kings North that will meet EGI's control, bypass, and maintenance requirements.   |  |                              |   |                                       |                             |  |                 |                    |                             |

| Toronto | 10 - Toronto         | Customer Connections | Pass                         |                      | 3405            | Area 10 - Apartment Traditional - New Construction* | 2032            | \$ 27,702                              | Apartment - An apartment customer is a multi-residential dwelling containing more than six units that is bulk-metered Issue/Concern: EGI is mandated to provide new or upgraded natural gas services to feasible residential and commercial/industrial customers. Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGD develops a customer additions forecast using a number of information sources: - Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long term plans EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. Enbridge reviews the following when determining feasibility: - The number of potential new customers - The consumption of natural gas by new customers; and - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing Assets: Generally, there are three components of capital investments needed to support customer addition requirements: - Installation costs related to mains, services, and meters - Material costs related to measurement and regulation equipment required to support customer growth  | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |

Feasibility is measured using the Profitability Index metric that ensures gas cost impacts are minimized. Without the required CAPEX captured under this program, EGI will not be able to provide new or upgraded natural gas services to feasible customers. Each year, EGI develops a customer additions forecast using a number of information sources:- Projections of potential customer growth resulting from current projects in different geographical areas of operation based on information from builders, developers and municipalities - Projections for customer growth based on housing start forecasts and other economic factors such as GDP growth, employment rates, and mortgage rates - Projections developed by external consultants specializing in population growth forecasting - Municipal long-term plans: EGI extends its gas main within its franchise area to serve new customers when economically feasible, as per criteria prescribed by the Ontario Energy Board (OEB) in the EBO 188 report. EGI reviews the following when determining feasibility:- The number of potential new customers - The consumption of natural gas by new customers - The cost of extending the gas main The OEB, through EBO 188, directs utilities to have an average PI of 1.0 or greater for their total portfolio of projects and that any one individual project must meet a PI of at least 0.8, ensuring the minimization of cross-subsidization among customers across all projects. This ensures that the costs of projects are recovered from the customer(s) who would directly benefit. Without this approach to system expansion, the utility would not collect enough revenue to fund its projects, and the shortfall would need to be recovered from all other customers. If the cost of the extension is not economically feasible, the applicant(s) will be required to pay a contribution in aid of construction (CIAC). EGI determines the CIAC amount and communicate with the applicant(s) in writing. Generally, there are three components of capital investments needed to support customer addition requirements:- Installation costs related to mains, services, and meters - Material costs related to mains, services and meters - Costs related to measurement and regulation equipment required to support customer growth.<br><br>Assets: All applicable assets.<br>Related Program: N/A  | Completed                              | Fail                         | Customer Connection-related projects are required to serve new customers connected in accordance with guidelines of EBO 188. Due to the the inability to offer non-gas IRPAs within the first-generation IRP Framework, IRPA's not applicable. | -                                     | -                           | -                                      | -               | -                  | -                           |
| Toronto | 10 - Toronto         | Growth               | Pass                         |                      | 7710            | McCowan Ave HP Reinforcement              | 2022            | \$ 19,374                              | Issue/Concern: Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure to maintain the capacity to meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers.<br><br>• Project Purpose/Need: This reinforcement is meant to support upstream and downstream load growth, bring back the flexibility EGI previously had in the system and to reduce dependency of other stations feeding the Intermediate Pressure (IP) network. Both McCowan and Southdale and South Unionville districts have been set to 40 psi and 50 psi respectively in 2016 to increase the tail-end pressures in the High Pressure (HP) network. Operations has posed concerns with leaving these stations set at their current outlet pressures for an extended period of time. If the reinforcement is completed, the set pressures can be increased to 55 psi, the downstream networks' intended pressure setting. Monitor points have been set up near the tail end of the HP network to determine if a reinforcement would be required in the near future. Mostly large volume customers and HP-IP district stations are fed off of the HP network and maintaining an inlet above 100 psi has always been an EGI standard (according to the PDR). As indicated, there are many alternate sources available, but the pressure tends to diminish as it approaches the tail end of the network. This constraint will become apparent in the event of a damage or repairs need to be performed on one of the alternate feeds. If the reinforcement is performed at the date indicated, key decisions can be made in the field with high levels of confidence.<br><br>• Pressure Issue/Concern: McCowan and Southdale District is approaching the minimum inlet pressure of 100 psi. There is a need to shift the flow to other sources in order to boost pressures near the tail end of the HP network.<br><br>• Risk If Not Completed: If the inlet to STN 36013A - McCowan and Southdale District or STN 32758A - South Unionville and McCowan District ( Markham ) fall below 100 psi during design conditions in 2021, approximately 5,000 customers downstream will be lost. Scheduled maintenance for both stations beyond 2017 will need to occur in summer months due to the instability of the HP feed. If this reinforcement is completed by the in-service date, either station could be taken offline for servicing without customer losses.<br><br>Updates from 2021 review<br><br>Assets (preferred option):<br>• Deferred to 2022 from 2021: Install XHP to HP station at Steeles Ave. and IBM. The station will have a designed inlet of 485 psi with an outlet of 175 psi. The primary feed for this station will come from Victoria Gate. The tie-in for the inlet will be off of the NPS 30 Steel Coated (SC) and the outlet will feed into the NPS 12 Steel (ST) HP on Steeles Ave. Approximately 25 m for the inlet and 25 m for the outlet will be required.<br>• Deferred to 2023 from 2022: Raise STN 36013A - McCowan and Southdale District from 40 psi to 50 psi. | Completed                              | Fail                         | N/A - Project in construction phase  | -                                     | -                           | -                                      | -               | -                  | -                           |

This will require tying into the High Pressure system with a Distribution Station that will require land purchase. DOE advises this must be executed by the end of 2023 as the system would be under minimum pressures in the winter of 2023/24 without the reinforcement. Further discussion with DOE with updated gas load information has resulted in a two-year approach with completion required by May 2024.<br>Assets: New Station and Gas Main<br>Related Investments: | Planned                                |                              |                               |                                       |                             |  |                 |                    |                             |  |

| GTA East  | 30 - Richmond Hill   | Growth      | Pass                         |                      | 7718            | North Bradford Reinforcement   | 2027            | \$ 725,874                             | Related Investments:<br>Issue/Concern/Opportunity - Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure to maintain the capacity to meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers. Project Purpose/ Need : Customer growth in the north end of Bradford will drive the timing of this project. Several polygons are visible in the draft plan of GIS which indicates that the growth will likely be in the near future. Significant existing development upstream of the proposed development reduces the pressures available to customers in the developments coming online in the future. Pressure issue/concern : The minimum system pressure is forecasted to be infeasible by 2019. Customer growth issue/ concern: As of 2017, there are 3,822 customers on this network. Without reinforcement, forecasted 578 customers may not be able to be added. Risk if not completed : System risk without reinforcement - Pressure at the tail end of the IP network is going to reach minimum pressure requirement by 2018-2019 - growing number customers upstream of the IP network are utilizing gas, which significantly drops the pressure by the time gas reaches the tail end of the network - approximately 3,900 customers may be impacted if minimum pressures are not satisfied Project Timing : LRP growth modeling indicates that the project will be needed in 2019, but due to the small amount of load addition needed to trigger this reinforcement it could come before or after this depending on when land is developed. Project Benefits Customer growth Benefit: with reinforcement, the north end of Bradford to continue to have customers added.<br>Assets : 2017- Replace Artesian Industrial Pkwy & 8th Line Station so that the minimum differential pressure is 45 psi or less. 2019- This project involves installing 750 m of 6" HP from Reagens Industrial Pkwy to Rogers Trail. | Planned                                |                              |                               |                                       |                             |  |                 |                    |                             |

| GTA East  | 30 - Richmond Hill           | Distribution Pipe | Pass                         |                      | 502190          | VSM - Yonge and Davis Dr West - Phase2                               | 2032            | \$ 3,361,499                           | Issue/Concern/Opportunity: The vintage steel mains have shown signs of declining health due to the cumulative effective of poor manufactured coating performance, construction practices, latent third party damages to pipe coating, and the effect of stray currents from transit infrastructure such as subway and streetcars. The current failure projection model is forecasting an exponential increase in the number of corrosion related failures, while the quantitative risk assessment and the 40-year risk projection are showing an aggressive increase in the safety risk associated with steel main failures. In addition to it age, vintage steel mains are also susceptible to accelerated degradation and/or higher risk of third party damage in the following ways: a. Compression couplings (mechanical fittings which are not welded onto the main) on steel mains that are not properly restrained or unrestrained could cause a loss of containment due to exposed points of thrust. In this case, the weight of the soil is required to hold the fittings in place. When the soil is disturbed, the pipe pulls out of the fitting, resulting in blowing gas through the open pipe end with the potential of full bore release of gas. b. Compression couplings on steel mains that are unknowingly isolated from the corrosion protection system could result in inadequate cathodic protection, leading to the assets' accelerated corrosion and potentially loss of containment. c. The existence of shallow blow-off valve assemblies that could be damaged during excavation activities. d. Reduction in the original depth of cover due to urban development could increase the potential of damages due to excavation activities and increased external loading. According to the codes and standards, a minimum depth of cover is needed to ensure the appropriate distribution of weight of transportation vehicles across pipelines is not exceeded. If the depth of cover is not appropriate, excessive stresses are introduced into the pipe, and failures could result. e. The continuous exposure of road salt and seasonal ground movement on bridge crossing assets that could result in accelerated corrosion and external loading/stresses. f. Lack of cathodic protection with pipe casings that could result in corrosion causing excessive stress or shorts on the carrier pipe that is in contact with the casing, which could lead to the loss of containment. g. Manufacturing defects associated with seam welds and fittings that are weak points in the distribution system and could result in a loss of containment due to prolonged exposure to stress and corrosion. h. Latent damages to pipe coatings that were never reported to EGD for repair and became active corrosion sites, which could hamper the effect of the corrosion protection system and result in accelerated corrosion and potentially loss of containment. SITE SPECIFIC CONCERNS: 1958 vintage IP steel main that is susceptible to the issues outlined above. Operations field personnel reported poor condition steel main in this area that was observed during previous maintenance activities . The vintage IP gas mains are in a highly populated residential area in Richmond Hill, which could drive up the consequence in the event of a failure. The compression outlet service tees on all the services in this area are highly susceptible to pull-out due to natural or external forces. | On Hold                                |                              | Future year replacement projects are in the queue for IRP Evaluation and will be assessed annually when the scope is confirmed |                                       |                             |  |                 |                    |                             |

The only outstanding item is to complete the remaining archaeological assessments for uncovered artifacts on the landowner's property where the pipe had been proposed to be placed.<br><br>Issue/Concern: Reinforcement projects broadly involve the installation of new or modification of existing gas distribution assets to maintain minimum required system pressure, maintain capacity, and meet customer demand. These projects are primarily driven by customer growth and system reliability considerations. Failure to implement reinforcement projects in a timely manner could lead to a potential inability to support increasing demands of existing customers and the addition of future customers.<br><br>Project Purpose/Need: This reinforcement addresses issues with the IP network, fed by ALMONTE DISTRICT (6A143A) and SCOTT ST. DISTRICT (6A206A). The interior subdivision piping are undersized, based on the growth predictions of customers' demands. Evidence of densification has become apparent through load sheets. Without the reinforcement, growth cannot be supported in the downstream system.<br><br>Pressure issue/concern: The minimum system pressure is forecasted to be infeasible by 2021. Customer growth issue/ concern: The Phase 1 reinforcement will enable the current system to continue adding new customers after the 10 customers from 2017-2019 as of the proposed in-service date, as per current known 11 customer growth projects equaling 870 m3/hr of load. However, Phase 1 only provides an additional 300m3/hr capacity for any additional growth outside of this and a Phase 2 reinforcement will be required for further system growth.<br><br>Assets: 3 options include 1.2 to 1.3 km of 4" XHP ST, or pressure increase of the system from 30 psi to 55 psi (involves 2.21 km PE IP, 10-15 km ST IP, 350 service replacements, 970 relights, 30 valve replacements).<br><br>Related Programs: 21353 (Almonte Reinforcement Phase 1) | Completed                              | Fail                         | N/A - Project Completed  | -                                     | -                           | -                                      | -               | -                  | -                           |

This program is for recoating work and hanger repair. The integrated Corrosion Operating Standard ST-17-813A-DDA9 was released 2020-11-25 and requires the following surveys: Annual visual, 5 year detailed. The standard outlines the following time frames: Bridge crossing – replace Per Engineering assessment per project plan; Bridge crossing – replace expansion joint / Ins flange within 24 months; Bridge crossing / paint pipe / repair hangers / replace casing end seal within 12 months.<br><br>Assets: High performance re-coating and hanger replacement and repair of bridge crossing.   | Completed                              | Fail                         | N/A - Investment Cancelled                                  | -                                     | -                           | -                                      | -               | -                  | -                           |
| GTA West            | Div_17 - Halton               | Distribution Stations | Pass                         |                      | 739155          | HALT: Georgetown TBS Rebuild, 21X-401R               | 2026            | \$ 1,994,884                           | Issue/Concern/Opportunity: Frost Heaving of outlet piping is resulting in damage to municipal roads. The station needs a heating system upgrade. In addition, a growth project had been scheduled in 2029 which would drive a station rebuild.<br>Justification: Frost heave issue needs to be resolved so as not to damage municipal infrastructure. Because a full rebuild is forecasted for 2029 it is recommended that the rebuild be advanced to reduce the total expenditure in this asset over time.<br>Asset - Georgetown TBS 21X-401R station rebuild was set for 2029 (HALT FBPSN 2029_21X-401R).  | Completed                              | Fail                         | Distribution station condition related, IRPA not applicable | -                                     | -                           | -                                      | -               | -                  | -                           |
| Head Office Support | Div_54 - Head Office Support  | Distribution Stations | Pass                         |                      | 503412          | CNG Station Project - #5                             | 2024            | \$ 2,378,925                           | Issue/Concern/Opportunity: Demand for CNG to support fleet operators in Owen Sound<br><br>Traditionally, fleet operators fuel their vehicles with gasoline or diesel. EGO promotes the use of natural gas to these customers as an alternate fuel source to provide a lower-cost and lower-emission fueling solution for vehicles such as garbage trucks, light duty vehicles, and transit buses. Business Development is responsible for the installation, maintenance, and the safe and continued operation of NGT stations assets for these customers. NGT stations differ in operation from distribution system stations as NGT stations use and store compressed natural gas (CNG) on site at up to 4000psi.<br>EGO has two general categories for NGT station types: Large, Mobile and Utility NGT stations and Small NGT stations (also referred to as VRAs). Large, Mobile and Utility NGT stations are similar in operation and will be evaluated for condition in the same manner.                               | Completed                              | Fail                         | See investment description, IRPAs not applicable for CNG    | -                                     | -                           | -                                      | -               | -                  | -                           |

Instead of tracerwire they installed some type of metallic tape. This has resulted in the mains and services being unlocatable</p> <p>Asset - 9.6km of vintage plastic and steel</p>   | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |
| Northern        | Div_46 - North Bay & Orillia | Distribution Stations                   | Pass                         |                      | 734305          | Station Rebuild A&B Program NORTHERN                  | 2023            | \$ 18,365,681                          | <p>Issue/Concern/Opportunity: The stations identified in this business case fall into one of the following categories: Below-ground box replacements: Removal of below-ground stations improves life cycle cost of stations due to accelerated corrosion related to salting and flooding, increased O&amp;M costs related to increased paint frequency, and the requirement for two at a box when work is performed. An additional and very important benefit to the elimination of below-ground boxes is the improvement of worker health and safety by eliminating the need to handle potentially contaminated water, and non-ergonomic work conditions. Obsolete Regulators: The criteria for this category is that there are no spare parts available, or parts are no longer approved for use on new installations, or a combination of poor performance and manufacturer availability. Low Pressure Districts: The failure of a low pressure district can have disastrous downstream impacts in the event of over-pressure protection failure. The outlets of these stations feed customers who may not have individual regulators at their meter sets. This additional line of defense is not present to protect customer piping. Double Boot-style Regulators: Stations with both operator and monitor boot-style regulators have a common failure mechanism as a result of debris in the gas stream. Replacement of one boot-style regulator with a non-boot regulator reduces the vulnerability of failure. Increased Capacity: Stations that are operating over designed capacity due to system growth are targeted for replacement to maintain gas supply. Loss of Containment: Station experiencing loss of containment (leaks) and high maintenance calls to repair equipment are also identified for replacement.</p> <p>Asset: District station assets.</p> | Completed                              | Fail                         | See investment description, IRPAs not applicable  | -                                     | -                           | -                                      | -               | -                  | -                           |

# EGI Asset Management Plan 2023 – 2032

Page intentionally left blank.

# 1 Executive Summary

## 1.1 Document Purpose

---

On January 1, 2019, Enbridge Gas Distribution (EGD) and Union Gas Limited (Union) amalgamated to form Enbridge Gas Inc. (EGI). EGI is comprised primarily of natural gas utility assets and operations that serve over 12 million consumers with 3.8 million residential, commercial and industrial connections in Ontario, serving over 313 municipalities and 23 First Nation communities. EGI's 180 billion cubic feet (approximately five billion cubic metres) of regulated storage assets are tied to large and growing demand centres in Canada and the U.S. and provide a critical link to low-cost natural gas supplies. The management of assets is important for the secure, safe and reliable delivery of energy to customers. Asset management at EGI ensures that value is realized through its assets while managing risk and opportunity.

The purpose of this Asset Management Plan (AMP) is to outline:

- Policy and strategies for establishing effective asset management for all utility assets within EGI's regulated operations
- How Enbridge strategies and stakeholder commitments (**Section 2.4**) are linked to asset class strategies
- Process and governance for asset management planning including linkages to EGI's processes for managing risk
- The approach to Integrated Resource Planning (IRP) and provide EGI's IRP Binary Screening and associated IRP alternative (IRPA) evaluation by project (Appendix B)
- Asset class objectives and life cycle management strategies
- Asset inventory, condition methodology, condition findings, risks, opportunities and renewal strategies
- Optimized 10-year capital plan required to manage assets from 2023 to 2032

This Asset Management Plan aligns with the ISO5500X industry standard, the Institute of Asset Management (IAM) and the Global Forum on Maintenance and Asset Management (GFMAM). This document is intended to meet the expectations of the Ontario Energy Board (OEB) as set out in the *Handbook for Utility Rate Applications, October 13, 2016* and the *Filing Requirements for Natural Gas Rate Applications, February 16, 2017* and EB-2020-0091 Enbridge Gas Inc. *Integrated Resource Planning Proposal, July 22, 2021*.

## 1.2 Overview of the Asset Management Plan

---

EGI's AMP includes all regulated assets inclusive of commodity-carrying assets directly related to the task of transporting natural gas and hydrogen from the source to the end-use customer, as well as assets that support business operations. The asset classes used to organize and define EGI's assets are Distribution Pipe, Distribution Stations, Utilization, Growth, Compression Stations, Liquefied Natural Gas, Transmission Pipe and Underground Storage, Fleet and Equipment, Real Estate and Workplace Services, and Technology and Information Services.

Investment decisions are categorized and managed on an asset class basis, where each asset class has a unique set of objectives and life cycle management policies that guide decision-making. With an understanding of the asset inventory and the evaluation of condition and risk, resultant strategies are identified and implemented.

**Figure 1.2-1** is an illustration of EGI's Asset Management Plan structure.

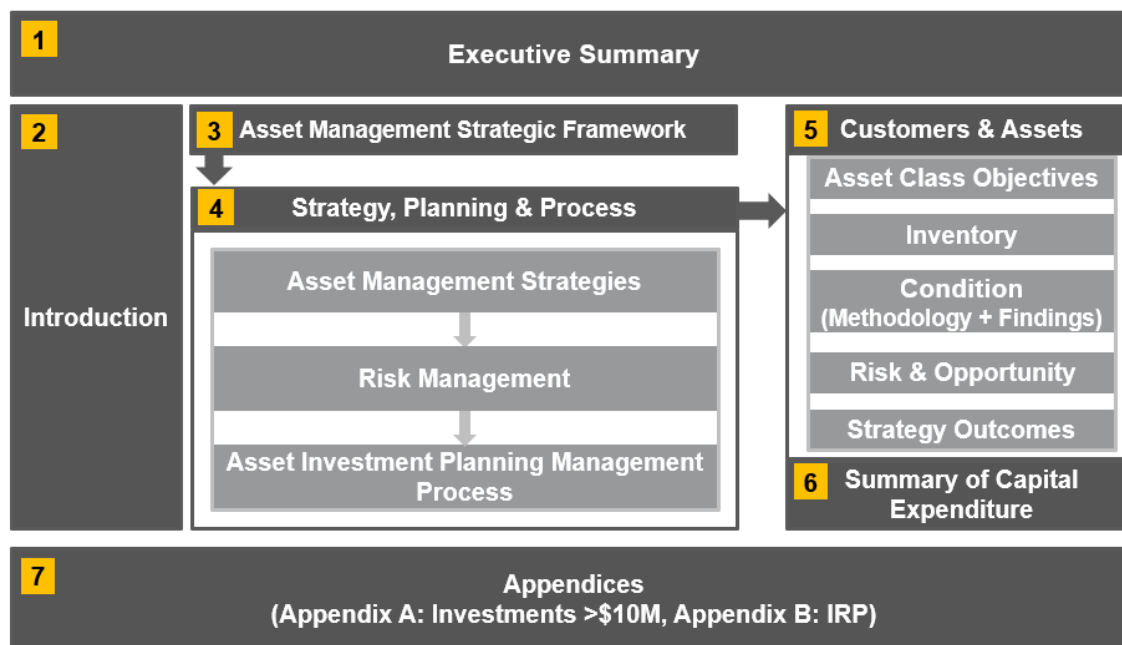

Figure 1.2-1: EGI's Asset Management Plan Structure

**Executive Summary (Section 1):** This section provides a summary of the Asset Management Plan.

**Introduction (Section 2) and Asset Management Strategic Framework (Section 3):** This plan starts with an introduction to EGI. It also highlights EGI's stakeholder commitment, the asset management framework and policy, updates and improvements from previous Asset Management Plans, Energy Transition, IRP, and the structure of the document.

**Strategy, Planning and Process (Section 4):** This section details the alignment of asset management at EGI with the Enbridge strategic priorities and includes EGI's asset management strategies, risk management and the Asset Investment Planning and Management (AIPM) process.

**Customers and Assets (Section 5):** This section details the following:

- EGI's customers and the customer growth projections
- Asset class objectives
- Asset class strategies
- Asset inventory
- Asset condition
- Risks and opportunities
- Strategy outcomes
- Capital investments to meet life cycle strategies

**Summary of Capital Expenditure (Section 6):** This section summarizes the 10-year capital investment plan for EGI by rate zone, outlines the optimization process and highlights key assumptions used for **Sections 5** and **6**. Note that projects where solution scopes are still under development are not currently included in EGI's 10-year portfolio of spend.

**Appendices (Section 7):** The appendices present supporting information for the Asset Management Plan. Appendix A includes descriptions of discrete investments with a Net Base Capex greater than \$10M in 2023 to 2032. Appendix B contains the IRP Binary Screening and associated IRPA evaluation statuses by project.

## 1.3 Advancing Asset Management

This document reflects the integrated utility's Asset Management Plan for the next 10 years, with assets for the rate zones (the EGD and Union North and South rate zones) being maintained separately for capital planning purposes in 2023 and as EGI from 2024 through to the end of 2032.

EGL continues to evolve its asset management practices to produce a comprehensive Asset Management Plan. As a result, the following changes were implemented:

- **Energy Transition**

This AMP incorporates assumptions for customer additions, peak hour demand and peak day demand, each of which have been adjusted to reflect EGL's current view of the impacts of the Energy Transition (Exhibit 1, Tab 10, Schedule 4). EGL acknowledges that energy transition is evolving and that investment decisions will be based on the best information at the time, including consideration of IESO's forecast electricity demand. EGL maintains its obligation to serve and is committed to implementing IRP with the intent of evaluating and comparing both supply-side and demand-side options to meet an energy system need in the immediate, medium and longer term.

- **Integrated Resource Planning (IRP)**

IRP represents a significant change to the facility planning that EGL has performed in the past and, as such, EGL is taking steps to develop processes, resources and capabilities to integrate new IRP requirements into its existing asset management process and other processes. EGL's AIPM process now incorporates the IRP assessment process. The IRP assessment step of the AIPM process (see **Section 4.3.4.1**), determines if an IRPA evaluation is required for each system need, and, if so, a cost-effective IRPA exists. Further details on the IRP assessment process can be found in EGL's IRP Annual Report.

Through the IRP assessment process, EGL has performed IRP Binary Screenings on eligible projects, consistent with the guidance provided by the OEB in its Decision. The IRP Binary Screening results and the associated IRPA evaluation statuses, by project, can be found in the **Appendix B – IRP**.

- **Alignment with Enbridge Inc.'s 2022 Enbridge Strategic Priorities**

Enbridge Inc. published a revised Strategic Plan in 2022. The alignment of EGL's Asset Management Policy, Asset Management Strategies and dimensions of risk have been reviewed to confirm alignment and are found in **Section 4**.

- **Organizational structure changes to align roles and responsibilities within the integrated utility**

The phase two Boundary and Real Estate initiative has been completed. EGL's regional boundaries and real estate assets across the province were reviewed to align current boundaries and strategically locate EGL's operating depots. The second phase of the initiative evaluated the area between the GTA West and Southeast regions. In January 2022, the regional borders were realigned to optimize the facilities within each new region.

- **Consolidation of asset data**

The systems of record for asset data in the Union rate zones include Maximo for meter, work, damage and condition data; SAP-PM for station work and asset data; GIS for pipe data; and CORR for corrosion data. Some data that supports the Asset Management Plan is now being migrated to a datamart as part of the integration of work and asset management systems. Ongoing documentation and consolidation of these datasets will enable EGL to analyze inventories more efficiently for the combined utility and better support the Integrity and Asset Management functions.

- **Evolution of asset condition and strategies**

**Section 5**, which addresses asset inventory, condition, risk/opportunity and strategy outcomes, has been updated to reflect the current understanding of assets. Specific project and program information is provided in **Section 6** to support each asset class's strategic plans. Key changes are:

- Review, comparison and integration where feasible of asset strategies, asset classes, asset condition, inventories, programs and processes between the two legacy companies
- Mapping the capital expenditures presented in **Section 5** to the asset class strategy
- Identification of outstanding items that remain in legacy programs until they can be integrated

- **Integration items to highlight**

Standards for installation, inspection, operation, maintenance, and asset decommissioning continue to be integrated. This work is ongoing; some legacy practices continue to be followed for each rate zone as analysis deemed it as appropriate for the assets at this time. Other design changes may be implemented on a go-forward basis. These new standards are reflected in this Asset Management Plan and will continue to evolve throughout the integration process. Specific integration efforts include:

- **Integrity Management Program**

EGL continues to evolve its Integrity Management Program based upon industry best practices and incident learnings. EGL has developed a quantitative risk model to assess the primary risk for pipeline assets within the distribution system which is being leveraged to identify and prioritize assets that are approaching end of life and

need to be replaced. Transmission pipeline assets already have a quantitative risk model; however, that model has also been enhanced with additional hazards and consequences, as well as the development of Safety Targets to further assess the risk of Transmission Integrity Management Program (TIMP) assets.

Detailed documented assessments (i.e., Integrity Plans) for assets or assets groups are being created to ensure the following:

- All potential hazards are considered.
- Appropriate inspection methods and timing are determined.
- Inspections are completed.
- Results are assessed.
- Any required repairs are made.
- The fitness for continued service is confirmed.

EGI has introduced the use of Safety Cases as an independent check that all hazards have been effectively considered and addressed. Safety Cases will initially be developed for a subset of the TIMP assets and expanded to other assets over time.

- **Fleet and Equipment**

EGI continues to standardize processes and procedures related to the assignment of vehicles for the appropriate roles, types of vehicles required to support employees in performing their roles, and vehicle maintenance and repair model.

- **Technology and Information Services**

TIS continues to support process and system integration while in parallel reducing EGI operational and cybersecurity risks. EGI continues to align systems, processes and procedures, prioritized based on business value (efficiency, safety/reliability, compliance) while adopting industry best practices regarding cloud computing where feasible.

- **Modelling enhancements from Distribution Optimization Engineering**

EGI has harmonized its approach to degree day forecasting and system modelling for growth; the resultant facility requirements form the basis for reinforcement forecast in this Asset Management Plan.

- **Operationalizing the Asset Plan**

As EGI develops the maturity of its Asset Management practice, greater focus is placed on measuring delivered work relative to planned work, highlighting the need for multi-year planning and the identification of resources required to execute the plan, including the resources required to scope, plan and obtain required approvals. Accomplishments of this initiative include:

- Documented and communicated Asset Investment Planning and Management (AIPM) processes, procedures, and accountabilities.
- Improved communication and training to promote consistency.
- Identification of incremental resources to support delivery of the asset investment plan.

- **10-Year Asset Management Plan**

This version of EGI's AMP considers a ten-year horizon with the understanding that the scope of investments in the earlier years of the plan are more refined than those in later years. Considering a 10-year window allows time to consider and develop feasible IRPAs to meet the identified system needs.

- **Value Assessment Quality Assurance Approach**

As the application of the Copperleaf value framework evolves, EGI has developed a continual improvement approach to validate and calibrate investment data, capture best practices, and to maximize value in the AMP. Emphasis was placed on applying data analytics practices and sense-checking investment data to better understand how EGI's value assessment processes are working and how they can be improved. Implementing this approach led to:

- Increased support for Asset Management optimization and calibration activities to ensure consistency and alignment of investment data.
- Greater stakeholder engagement and transparency of value across EGI's portfolio of opportunities.
- Identification and documentation of improvements to the Copperleaf value framework.

- **Greenhouse gas emission reductions**

Enbridge continues to evaluate and implement facility emission reduction opportunities by ensuring initiatives effectively balance security, safety, operational reliability, customer preferences, compliance obligations and anticipated future regulations. In the evaluation of system expansion alternatives, the cost of fuel and carbon are considered along with operational requirements. These opportunities are tracked through the GHG Scope 1 & 2 Working Group. The GHG Scope 1 & 2 Working Group will identify and review potential opportunities and strategies to achieve cost-effective GHG reductions, which are incorporated into asset class life cycle strategies, as well as operating practices, equipment modernization and innovation, and emerging policies and regulations. EGI's efforts in reducing its environmental footprint are closely tied to the work outlined in this Asset Management Plan.

## 1.4 Capital Expenditure

The EGI capital plan was optimized from 2023 to 2032 using the Asset Investment Planning and Management (AIPM) process (outlined in **Section 4.3**). EGI's AIPM process uses Copperleaf as the asset investment planning tool. The result addresses the organization's asset needs and includes known risks and opportunities requiring action over the next ten years.

In total, 1,500 EGD RZ investments and 1,1901 Union rate zone (RZ) investments were included in the optimization of the 10-year plan. In preparation for optimization, comprehensive governance reviews were completed on proposed investments using the following criteria:

- Investment scope met EGI's capitalization policy.
- Investments presented a well-articulated purpose, need and timing aligned with asset class objectives and life cycle management strategies.
- Investment scope definition and alternatives adequately addressed project risks and/or opportunities.
- Investments supported the asset management principles of balancing risk, cost and performance.
- Execution risks were reasonable (resource capacity).
- Initiatives identified as mandatory were justified, based on:
  - Exceeding an established risk threshold
  - Third-party relocation
  - Program work with sufficient history and risk to warrant continuation
  - Projects that meet the economic feasibility tests in EBO 188 and EBO 134
  - Compliance requirements
  - Investments that were already executing with costs continuing into 2023 to 2032 and the remaining work could not be shifted.

### 1.4.1 Capital Considerations

The optimization process is based on EGI management setting a capital constraint or threshold from which a portfolio of work driven by asset needs is defined. The capital constraint is determined based on the asset needs and financial considerations. Determining the capital constraint involves EGI's Asset Management, Finance and Regulatory departments. To complete EGI's latest portfolio optimization, EGI considered optimization constraints for 2023 and for the remainder of the 10-year plan separately.

For 2023, the assets for EGD RZ and Union North and South RZs, were maintained separately for capital planning purposes as 2023 is the final year of the approved five-year (2019 to 2023) deferred rebasing term from the MAADS Decision (*EB-2017-0306/EB-2017-0307*). For the 2024 to 2032 optimization constraint, EGI considered historical spend levels, inflation, smoothing the impact to ratepayers and the capital to meet asset class strategy needs.

EGI's optimization constraints were determined through the following efforts:

- For 2023, EGI recognized that two significant projects are expected to go into service in that year - Dawn to Corunna Project (see **Appendix A, Pg. 1**) and the Panhandle Regional Expansion Project (see **Appendix A, Pg. 55**). EGI first attempted to leverage the materiality threshold as the constraint for 2023 but was unable to accommodate the significant volume of compliance, must-do, and in-flight work. In the end, the 2023 Budget was constrained to \$1.5B, the amount that had previously been included in the long-range plan created in 2022.
- To set a constraint for the remainder of the 10-year plan, EGI looked at scenarios between the 2023 Materiality Threshold of ~1.4B and the historical average spend of ~\$1.17B<sup>1</sup>. In each case an escalation of 2% for inflation was

<sup>1</sup> Historical average spend was calculated using the average of the 2019-2021 actuals and 2022 forecast.

applied (see **Table 1.5-1** for inflation assumptions). Through the process of moving the optimization constraint line downwards from \$1.4B to \$1.1B, EGI examined:

- Implications to asset class strategies
- Implications to in-service capital (as a proxy for impact to ratepayers)
- Implications for the management of identified risk
- Ability to complete mandatory work
- Ability to complete work that supports the energy transition
- Ability to complete work that is in keeping with customers' stated preferences
- Organizational capacity to complete work

Through consultation with a wide range of internal stakeholders, EGI determined that the 2024-2032 optimization constraint of \$1.2B with an annual escalation of 2% for inflation allowed for safe and reliable outcomes through execution of EGI's asset class strategies. EGI had to treat specific significant investments (Dawn C Compression Lifecycle in 2026 [see **Appendix A, Pg. 3**] and Dawn-Parkway Expansion [Dawn-Enniskillen NPS 48] in 2029 [see **Appendix A, Pg. 53**]) as exceptions to the optimization constraint in order to obtain the optimized result in those years.

The increase in capital for 2024 relative to the historical average is attributed to the following:

- +\$129M in market driven growth with several large growth investments identified with spend in 2024 including: Panhandle Regional Expansion Project (PREP), PREP: Leamington Interconnect, Wheatley 1B PREP Reinforcement, East Kingston Creekford Road Reinforcement and the Dawn Parkway Expansion Project (Kirkwall-Hamilton NPS 48). The timing for these investments is based on the market requirements, EGI will evaluate the market driven investments for technically and economically feasible IRPAs.
- +\$107M in planned replacements have shifted into 2024 to provide additional time for EGI to assess and adequately demonstrate the condition of the pipelines as an outcome of the St. Laurent LTC Decision.
- +\$95M in compliance related investments including increases to meter and regulator exchanges due to increased costs for meters and large numbers of meters reaching expected end of seal life. In addition, updated hazard assessments completed under EGI's Transmission Integrity Management Program have identified the need to review and mitigate high and moderate uncertainties in the fitness-for-service conclusions of the review.

Optimization constraints lower than \$1.2B (i.e., \$1.1B) caused the optimization to fail as they do not accommodate all investments with fixed timing. Examples of investments with fixed timing that must be executed in a given year include:

- Compliance work must be completed in accordance with rules and regulations, deferring this work could result in EGI being out of compliance.
- Relocations must be completed in a given year order to ensure that the work triggering the relocation is completed. Relocation projects are subject to the timing of the work triggering the relocation and as such timing of these projects is fixed.
- Reinforcements have fixed timing because absent the reinforcement, EGI would not be able to attach customers to its system after the reinforcement is required.
- Executing work has fixed timing as these projects have already commenced and therefore cannot be deferred.

Lowering the capital constraint would require EGI to reduce programs that directly maintain EGI's safe and reliable operations, for example:

- Compliance driven work, including integrity management work and meter exchanges.
- Program work with sufficient history and risk to warrant continuation, including AMP fitting replacements, inside regulator and ERR programs, distribution station replacement work, vehicle replacements and TIS infrastructure.
- Investments prioritized through EGI's Risk Management Process (**Section 4.2**).
- Copperleaf was used to optimize the 1,500 EGD RZ investments and 1,901 Union RZ investments in the initial pre-optimized ask. Using the optimization constraint values, the optimal capital timing was determined for proposed investments, as described in **Section 4.3.3**.
- The Decision with Reasons in the St. Laurent Ottawa North Replacement Project (EB 2020-0293) led to two subsequent changes to this AMP to ensure that there was adequate time to collect condition information and consider risk implications – St. Laurent Phases 3 and 4 (see **Appendix A, Pg. 13 & 14**), and Wilson Avenue Vintage Steel Replacement (see **Appendix A, Pg. 10**). Investments in the 10-year plan that had sufficient timing for further, cost effective and prudent evaluation will continue to be assessed without prejudice to support the resultant investments. The LTC decision for St. Laurent is not expected to impact the Vintage Steel Replacement Program as this program and the associated selection of pipe replacements are based off of predictive analytics (condition and risk from the DIMP Risk Model as described in **Section 5.2.3.6.3.2**).

## 1.4.2 Optimization Results

**Figure 1.4-1** presents the 10-year capital requirements by asset class with four years of historical spend for EGI. The final 10-year portfolio of spend was reviewed and approved by the Vice President of Engineering and the Asset Management Steering Committee.

**Figure 1.4-1: Final Ten Year Plan by Asset Class - EGI (Capital Expenditure)**

**Note:** Historical actuals include both Capital Pass Through (CPT) Mechanism, ICM projects and integration capital. The total forecasted capital expenditure categorized by asset class depicted in **Figure 1.4-1** is comprised of each investment's direct costs and the associated overheads. Asset class historical spend profiles in 2019 and 2020 do not include associated overheads; for this reason, overheads are identified as a separate category historically. Due to the timing of the 2022 Forecast data, the 2023 Budget and 2024 Forecast include investments that have shifted out of 2022 that are also captured in the 2022 Forecast, for example St. Laurent Ph 3/4.

## 1.5 Assumptions

The 10-year capital plan is based on the best available information at the time of completion. Key assumptions detailed in the tables below provide a basis for interpretations.

**Table 1.5-1: Assumptions for All Categories**

| Assumption   | Basis for Assumption  |
|--|---|
| Optimization results are based on available information as of March 2022.* | Based on EGI's Optimize Portfolio of Solutions process, the portfolio of spend is determined through the completion of Copperleaf leveling and subsequent reviews. Results are based on best available information.<br>*The timing of St. Laurent Ph 3/4 and Wilson Avenue Vintage Steel Replacement project (see Appendix A, Pg. 10, 13 and 14) was updated in May 2022 following LTC Decision (EB-2020-0293). |

| Assumption  | Basis for Assumption  |
|---|---|
| Future costs are valued at 2022 Present Value.                                  | Current practice forecasts projects based on 2022 rates.  |
| Future costs do not include inflationary measures.                              | Normal inflationary measures and impacts such as rising material costs, foreign exchange and labour are expected to be covered within investment contingency. Incremental shifts in inflation caused by global supply chain shortages, pandemics or other unusual circumstances have not been considered.<br>A small number of programs with defined scope/unit rates have included a factor where information was available to inform the assumption (such as meter purchases and vehicle purchases).                    |
| All cost estimates are based on available information as of March 2022.         | Using EGI's AIPM process, these requirements will be reviewed and revised as required.  |
| All Risk Assessments are based on risk models and methodology as of March 2022. | Using EGI's Risk Management process, EGI's significant operational risks are reviewed quarterly and revised as required.  |
| Projects in flight that span over multiple years must continue until complete.  | Once a project is in progress it is inefficient and costly to terminate.  |
| Historical actual costs are valued at years' actual value.                      | Historical values are not adjusted to be expressed in present value.  |
| The proposed capital expenditures represent facility alternatives.              | As this is the first year that EGI has applied the IRP Framework to the AMP, EGI's IRP assessment process (see <b>Section 4.3.4.1</b> ). This IRP assessment process took place concurrent to the identification of the facility-based investments that underpin the AMP's 2023-2032 Capital Expenditures.<br>Future iterations of the AMP will have proposed capital requirements that incorporate the comparison of viable facility and IRP alternatives to the extent possible prior to the next iteration of the AMP. |

Table 1.5-2: Renewal Assumptions

| Assumption   | Basis for Assumption   |
|--|--|
| Asset health provides a reasonable representation for asset condition and remaining asset life for forecasting purposes. | Reliability engineering is used to understand asset health. Based on projected life cycles, consequences of failure, tacit knowledge and asset data, risk. Renewal projects are planned to reduce this risk to the lowest practicable level. |

Table 1.5-3: Customer Growth Assumptions

| Assumption  | Basis for Assumption  |
|---|---|
| Customer growth is forecast using historical trends, and economic projections for the planning period.  | The customer growth forecast considers projected housing starts, municipal growth forecasts, general economic indicators and projections, localized trends and macro-economic factors.<br>EGI is cognizant that there may be impacts to customer growth forecasts based on climate/carbon policies. |
| Load forecasting is based on current understanding of temperature inputs described in Exhibit 3, Tab 2, Schedule 3 and estimated customer consumptions. | EGI has proposed a harmonized forecast methodology as part of this rebasing application.<br>The estimated customer consumptions have historical Demand Side Management (DSM) built into the load forecast based on past results.  |

Table 1.5-4: Solution Planning Assumptions

| Assumption   | Basis for Assumption   |
|--|--|
| <b>Budgeting and forecast are determined through the Solution Planning &amp; Value Assessment process.</b> | Estimates are determined considering region and work type to accurately forecast. Appropriate project planning processes are followed. |

## 2 Introduction

### 2.1 Purpose of the Asset Management Plan

---

On January 1, 2019, Enbridge Gas Distribution (EGD) and Union Gas Limited (Union) amalgamated to form Enbridge Gas Inc. (EGI). EGI is comprised primarily of natural gas utility assets and operations that serve over 12 million consumers with 3.8 million residential, commercial and industrial connections in Ontario, serving over 313 municipalities and 23 First Nation communities. EGI's 180 billion cubic feet (approximately five billion cubic metres) of regulated storage assets are tied to large and growing demand centres in Canada and the U.S. and provide a critical link to low-cost natural gas supplies. The management of assets is important for the secure, safe and reliable delivery of energy to customers. Asset management at EGI ensures that value is realized through its assets while managing risk and opportunity.

The purpose of this Asset Management Plan (AMP) is to outline:

- Policy and strategies for establishing effective asset management for all utility assets within EGI's regulated operations
- How Enbridge strategies and stakeholder commitments are linked to asset class strategies
- The integration of IRP and provide EGI's IRP Binary Screening and associated IRPA evaluation statuses by project (**Appendix B - IRP**)
- Process and governance for asset management planning including linkages to EGI's processes for managing risk
- Asset class objectives and life cycle management strategies
- Asset inventory, condition methodology, condition findings, risks, opportunities and renewal strategies
- Optimized 10-year capital plan required to manage assets from 2023 to 2032

This Asset Management Plan aligns with the *ISO5500X* industry standard, the Institute of Asset Management (IAM) and the Global Forum on Maintenance and Asset Management (GFMAM). This document is intended to meet the expectations of the Ontario Energy Board (OEB) as set out in the *Handbook for Utility Rate Applications, October 13, 2016* and the *Filing Requirements for Natural Gas Rate Applications, February 16, 2017* and EB-2020-0091 Enbridge Gas Inc. *Integrated Resource Planning Proposal, July 22, 2021*.

### 2.2 Company Purpose, Vision, Values and Strategic Priorities

---

#### 2.2.1 Purpose, Vision and Values

Asset management supports Enbridge's Purpose, Vision and Values (see **Figure 2.2-1**) by improving the Company's ability to operate safely and reliably, ultimately maintaining the satisfaction of customers and other stakeholders. Asset management provides the necessary structure to make informed asset decisions and execute the resultant actions. In this regard, it is imperative that the framework of asset management at EGI is aligned with Enbridge strategic priorities.

**Figure 2.2-1: Enbridge Purpose, Vision and Values**

**Purpose:** *We fuel people's quality of life.*

Enbridge delivers energy where and when it is needed and does so reliably, efficiently and always with the safety of employees, the public and the environment in mind. Asset management at EGI ensures these elements of quality are embedded within EGI's decision-making framework.

**Vision:** *To be the leading energy delivery company in North America.*

Enbridge demonstrates leadership in safety, environmental stewardship, customer service, its people, community investment, and shareholder value. Asset management ensures asset value is realized by making optimal, transparent and defensible decisions that ultimately provide value to customers and shareholders and exemplify leadership among North American energy delivery companies.

**Values:** *Safety, Integrity, Respect, Inclusion.*

Enbridge continues to build on its foundation of operating excellence by adhering to a strong set of core values—*Safety, Integrity, Respect and Inclusion*—in support of its communities, the environment and its people. Asset management helps maintain the integrity of assets to ensure Enbridge operates safely and reliably, respecting customers and stakeholders.

## 2.2.2 Strategic Priorities

Enbridge's 2022 Enterprise Strategic Priorities (see **Figure 2.2-2**) are defined to enable the organization to achieve its vision to be the leading energy delivery company in North America. Asset management actions and decisions align with these strategic priorities, contribute to Enbridge's success, and support the company purpose of fueling people's quality of life, while maintaining the foundation of the business, supporting the energy transition and positioning the company for future growth.

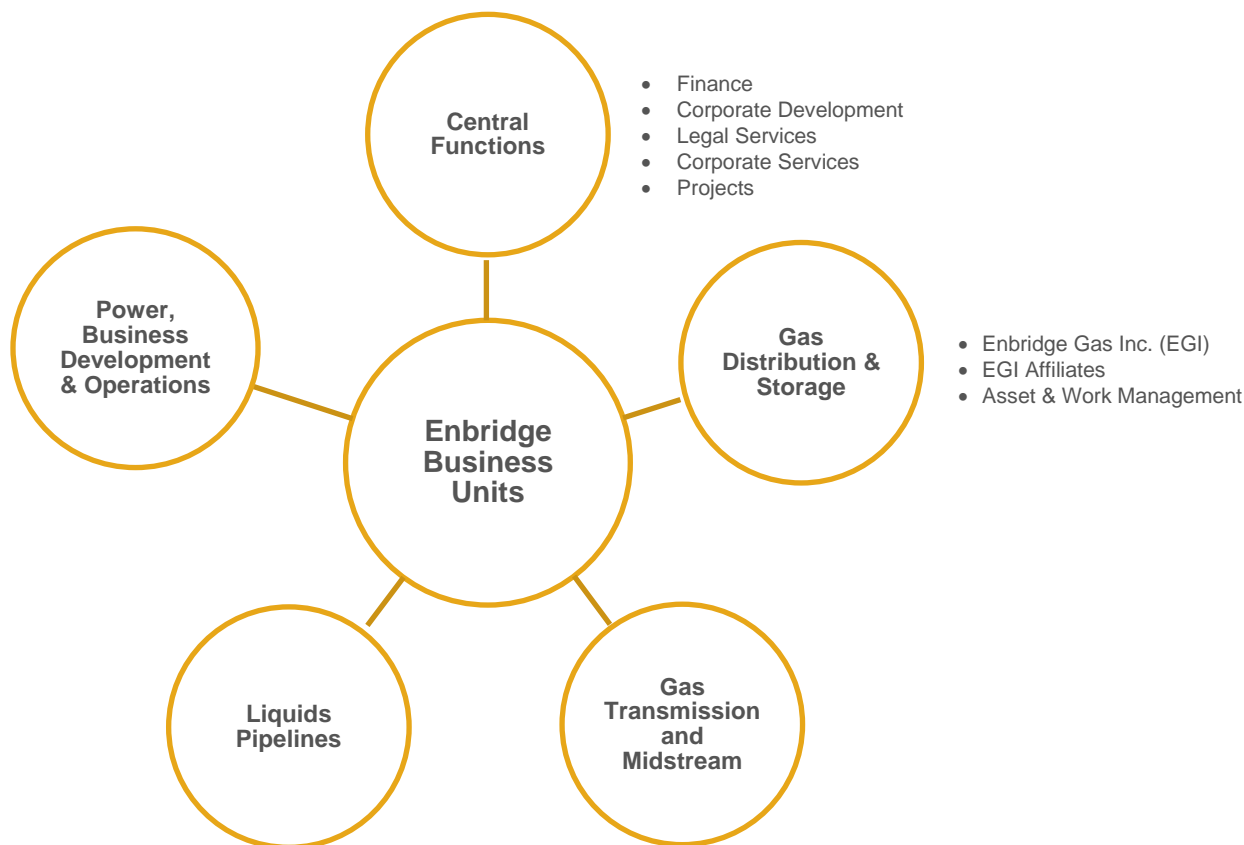

**Figure 2.2-2: Enbridge Enterprise Strategic Priorities**

## 2.3 Organization and Structure

Enbridge carries out its activities through four core business units: Liquids Pipelines; Gas Transmission and Midstream; Power, Business Development & Operations; and Gas Distribution & Storage (GDS) (see **Figure 2.3-1**). The GDS business includes EGI and other affiliate companies.

In addition, Enbridge's Central Functions teams (i.e., Finance, Corporate Development, Legal Services, Corporate Services, and Projects) enable business units to achieve their strategic goals.

**Figure 2.3-1: Enbridge Business Units**

EGI within Ontario is regulated by the Ontario Energy Board (OEB). This Asset Management Plan outlines the management of EGI's regulated assets in Ontario.

## 2.3.1 Enbridge Gas Inc.

EGI serves over 3.8 million residential, commercial, and industrial customers in Ontario delivering 30% of Ontario's energy needs and heating 75% of homes in the province. EGI's distribution system supplies gas to commercial, agricultural, industrial and power generation applications that contribute to the economic health of Ontario. EGI is North America's third largest gas utility by customer count. EGI's franchise area is divided into seven operating regions as shown in **Figure 2.3-2**:

- Northern Region covers the legacy Union Northwest and Northeast districts.
- Southwest Region covers the legacy Union Windsor/Chatham and Sarnia/London districts.
- Greater Toronto Area (GTA) West and Halton covers the Western Greater Toronto (legacy EGD Area 20, 50) and legacy Union Halton districts.
- Toronto Region covers the city of Toronto (legacy EGD Area 10).
- GTA East Region covers the eastern Greater Toronto Area (legacy EGD Areas 30 and 40).
- Eastern Region covers legacy EGD Area 60, 90 (Gazifère<sup>2</sup>) and the legacy Union Eastern district.
- Southeast Region covers legacy Union Waterloo/Brantford and Hamilton districts, and Niagara (legacy EGD Area 80).

EGI has storage and transmission assets which receive, store and transport natural gas for markets in Ontario, Quebec, the Maritimes, and major U.S. natural gas-consuming areas. EGI's Dawn Hub in southwestern Ontario is connected to most of North America's major natural gas basins, including gas supplies in the Western Canadian Sedimentary Basin and the Utica and Marcellus producing regions in the U.S. It is similarly connected to the major demand markets in those areas, more than half a dozen major pipelines connect at Dawn.

EGI transports gas from the Dawn Hub to the GTA through its West, Central, and East transmission operations areas.

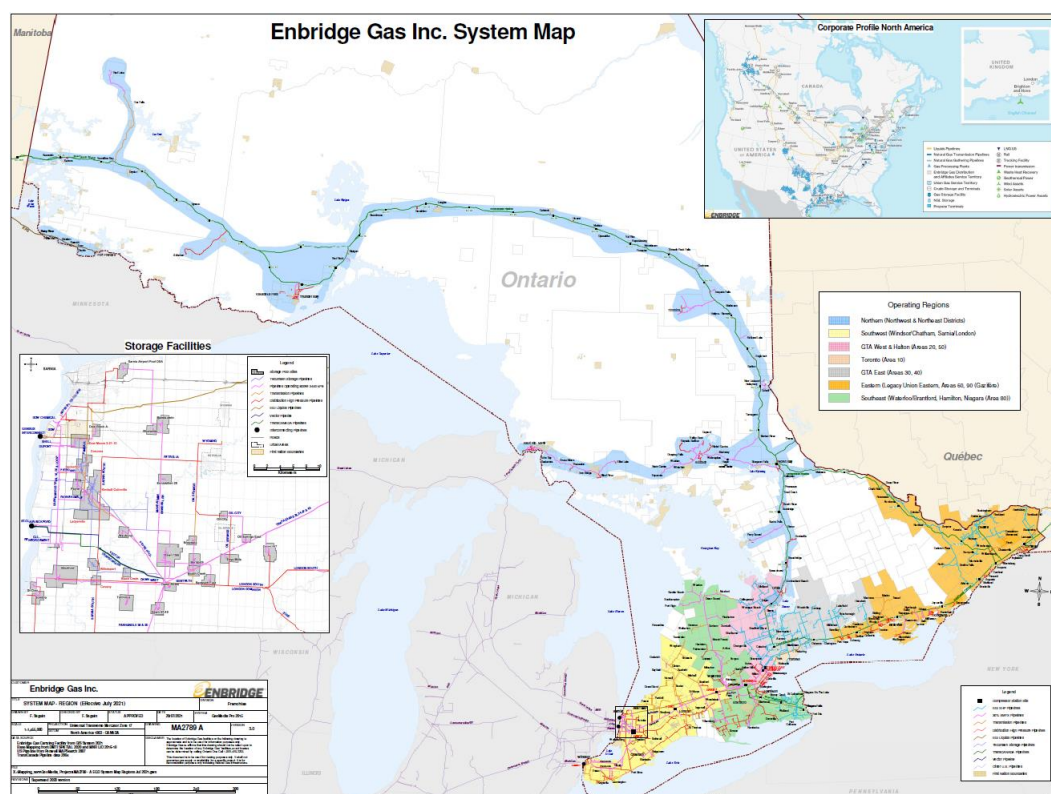

Figure 2.3-2: EGI Operating Regions

<sup>2</sup> Gazifère assets are not in scope of this Asset Management Plan.

## 2.4 Stakeholder Commitment

EGL is committed to its customers, regulatory bodies and other stakeholders to identify, build and maintain mutually beneficial relationships. EGL engages its stakeholders to maintain awareness and drive involvement at the inception of new projects and throughout regular operations. Understanding stakeholders and their concerns is critical to making good business decisions and mitigating risk. There is a direct link between EGL's ability to listen and respond to public concerns, and the ability to manage costs and regulatory approval timelines. Asset management at EGL and this Asset Management Plan are a direct demonstration of the Company's commitment to its stakeholders to ensure asset value is realized and optimal decisions are made based on risk and opportunity. See Exhibit 1, Tab 10, Schedule 5, Section 2 for detail on how stakeholder commitment is incorporated into energy transition.

### 2.4.1 Customer Engagement Results

As per the Rate Handbook released by the OEB on October 13, 2016, utilities are expected to develop an understanding of their customers' needs and preferences and to incorporate the findings into their Utility System Plan (USP). EGL's Asset Management Plan is a component of the USP (refer to Exhibit 2, Tab 6, Schedule 1).

To this end, EGL conducted an extensive customer engagement process throughout 2021 and early 2022 (refer to Exhibit 1, Tab 6, Schedule 1).

Further to the results described in the **Overall Results** of Exhibit 1, Tab 6, Schedule 1, additional results referenced in this AMP are summarized here:

- **The majority of residential customers agree that EGL should actively invest in low-carbon solutions** including energy efficiency technologies, hydrogen gas, renewable natural gas and carbon capture, utilization and sequestration (CCUS). These solutions would help reduce impacts on the environment and that EGL is well positioned to support the development of low-carbon options and solutions.
- **Compression Stations:** The majority of residential customers and business customers would prefer to replace aging compressor stations to minimize the risk of failure, knowing that the compressor replacements would translate into an increase in their natural gas bill during the 2024 to 2028 period.
- **Vintage Steel Replacement Program:** Over half of residential customers and business customers prefer to increase spending on the Vintage Steel Replacement Program in order to help prepare the system for the future by proactively ramping up spend, which would increase their bills.
- **Hydrogen Gas:** Over half of customers prefer that EGL implements plans to increase the use of clean hydrogen as a tool for reducing GHG emissions in Ontario, which would increase their bills.
- **Advanced Meter Infrastructure:** The majority of customers support the installation of Advanced Meter Infrastructure in order to achieve the enhanced benefits outlined in Exhibit 2, Tab 7, Schedule 2.

These results demonstrate that customers are aligned with EGL's commitment to the safe, reliable, cost-effective and environmentally responsible provision of energy. It also informs and reinforces EGL's asset management decision-making framework. EGL's values and guiding policy statements, outlined in **Section 3.1.2** align with the preferences of customers in the following ways:

- Asset management goals include employee and public safety, compliance, financial performance, value-based decision-making that incorporates environmental sustainability and the transition of customers' needs to low-carbon energy solutions and value to stakeholders.
- EGL is committed to prudent value-based decision-making for all asset-related investments on a holistic evaluation of risk, cost and performance.
- EGL is committed to understanding and delivering value to its customers.

### 2.4.2 Indigenous Consultation and Engagement

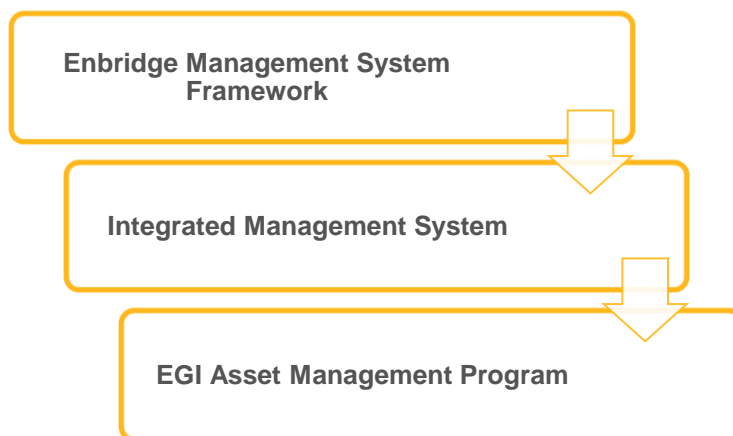

EGL is committed to building respectful and foundational relationships with Indigenous groups. In Ontario, the Community and Indigenous Engagement (CIE) team supports all utility engagement, and regularly interfaces with approximately 50 Indigenous communities both currently being served by natural gas and prospective service communities, and communities in proximity to EGL operations. EGL's life-cycle approach to engagement includes standards of practice for formal consultation on proposed projects, but also engagement for building respectful, constructive and enduring relationships that foster trust with and generate benefits for Indigenous groups over the life-cycle of EGL assets.

For new asset initiatives, EGI aims to enhance its existing relationships built through ongoing engagement and open a dialogue that will inform decision-making from the project proposals and design phase through to construction, operations, and maintenance to safely remove a pipeline from service at the end of its useful life. EGI engages in forthright and sincere consultation and engagement with Indigenous Peoples about EGI's projects and operations through processes that seek to achieve early and meaningful engagement so communities' input can help define projects and plans that may traverse Treaty lands and traditional territories of Indigenous Nations.

### 3 Asset Management Strategic Framework

This Asset Management Plan incorporates the Enbridge Management System Framework and EGI's Integrated Management System (IMS) requirements. It demonstrates alignment (see **Figure 3.0-1**) with the *ISO 5500X* standard and the Institute of Asset Management (IAM) Conceptual Asset Management Model (see **Figure 3.1-1**).

**Figure 3.0-1: Alignment of Standards and Requirements**

The IMS describes how EGI manages its business to be safe and reliable. Specifically, the IMS outlines high-level management expectations common across the organization and considers over 300 management system requirements from several regulatory, corporate and business unit sources, as well as industry standards. The Asset Management Program, one of eight management programs that comprises the IMS, provides more detail on how the program meets its regulatory and corporate obligations related to safety and operational reliability and aligns with the Enbridge Asset Management Program.

The IMS is predicated on the underlying principle of striving for continual improvement through the implementation of the Plan-Do-Check-Act (PDCA) quality cycle. As a model for continual improvement, EGI applies the PDCA cycle (see **Figure 3.0-2**) to macro- and micro-level activities of the organization. The cycle outlines the activities required to ensure that changes are executed effectively and that continual improvement opportunities are identified.

PDCA principles are:

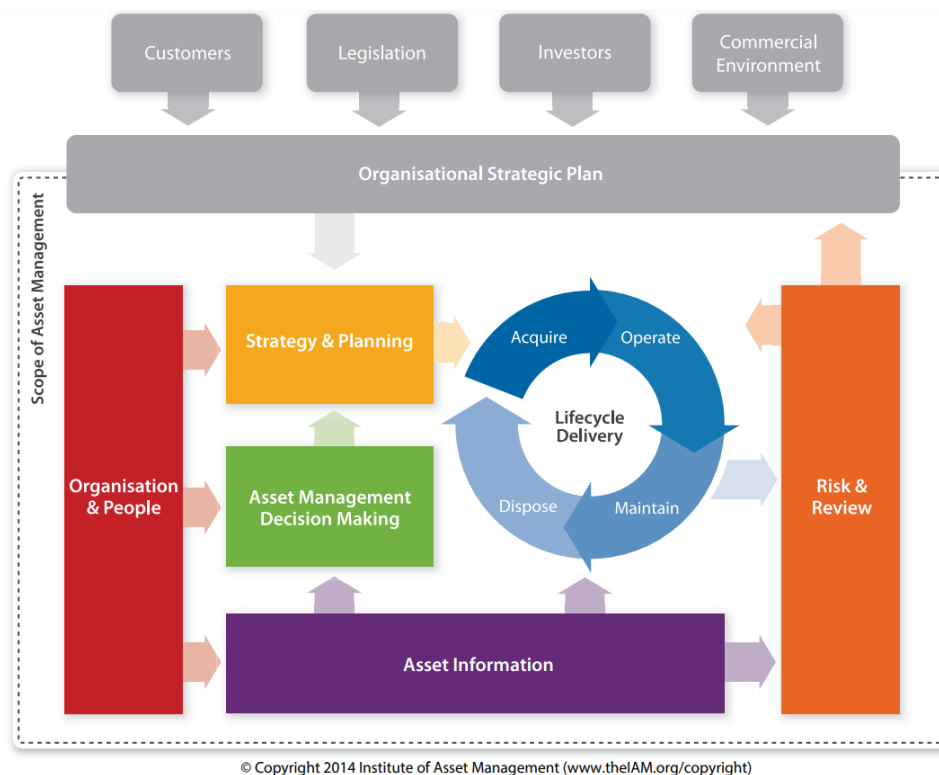

- **Plan:** Establish objectives and processes necessary to deliver results in accordance with expected outcomes and performance targets.
- **Do:** Implement the plan and execute the process.
- **Check:** Monitor the actual results using assessments, internal reviews and audits to compare against the expected outcomes and to ascertain any differences.
- **Act:** Apply corrective and preventive actions on significant differences between actual and planned results. Analyze differences between actual and expected outcomes to determine root causes and how to improve the process.

**Figure 3.0-2: Plan-Do-Check-Act Cycle**

### 3.1 Asset Management Framework

The IAM Conceptual Asset Management Model (see **Figure 3.1-1**) has been used to build and implement an asset management framework at EGI to balance risk, cost and performance through the entire asset life cycle. The IAM model guides EGI in the development of an asset management framework aligned to *ISO 5500X* and demonstrates the connections between the subjects of asset management and the elements of the IMS. This model also provides a visual representation of how the asset management discipline connects the various elements and functions across the organization. It further defines asset management planning as the detailed activities, resources and responsibilities for the achievement of asset management goals. This guidance has been used to develop the content and strategy of this Asset Management Plan.

**Figure 3.1-1: IAM Conceptual Asset Management Model**

*Asset Management - An Anatomy Version 3* interprets the *ISO 5500X* standard and provides a practical way to implement its requirements by breaking them down into 39 subjects grouped into 6 subject groups in alignment with the 6 major asset management components:

**Strategy and Planning:** The adoption and maintenance of a governance framework used to align Asset Management Plans and decision-making within the Enbridge's overall strategic objectives.

**Organization and People:** The development and maintenance of an adequate supply of competent and motivated people, in key asset management roles across all levels, to support the organization in delivering asset management objectives.

**Life Cycle Delivery:** The establishment of clear ownership, accountabilities, policies and processes to manage all physical assets throughout their entire life cycle.

**Risk and Review:** The identification, assessment, evaluation, treatment and monitoring of risks, resulting in prudent resource allocation and balancing risk, cost and performance.

**Asset Management Decision-Making:** The organization's approach to making decisions on design, maintenance, operation and disposition in a structured, defensible and repeatable process. This framework allows for the balancing of risk, opportunity, cost and performance in making asset investment decisions over the whole life cycle of the asset.

**Asset Information:** The availability of the right systems, processes and data to support asset management. This is foundational to all other asset management capabilities.

### 3.1.1 Enbridge Strategic Priorities

The Enbridge Strategic Priorities (see **Section 2.2.2**) enable the Company to achieve its vision to be the leading energy delivery company in North America. Asset management actions and decisions align with these strategic priorities and contribute to Enbridge's success. They support Enbridge's purpose of fueling people's quality of life, while maintaining the foundation of the business, positioning the organization for the future and supporting EGI's ambition to be the utility and sustainable energy provider of choice.

The Asset Management Policy translates Enbridge's strategic priorities into a series of policy statements that guide all aspects of the asset management system.

### 3.1.2 Asset Management Policy

#### Vision and Mandate

Enbridge exists to fuel people's quality of life with a long-term vision to be the leading energy delivery company in North America. Enbridge Gas Inc. (EGI) is committed to the safe, reliable, cost-effective and environmentally responsible provision of energy to its customers. At the core of this commitment is the effective stewardship of EGI's assets through governance, policy, and practices. EGI will apply leading asset management practices to effectively manage the life cycle of assets as EGI supports the transition to a low-carbon future. Optimal value will be delivered to customers and stakeholders through a sustainable investment plan that balances cost, risk and performance.

#### Scope

The Asset Management Program considers all EGI assets, inclusive of commodity-carrying assets directly related to the task of transporting natural gas and low-carbon energies from the source to the end-use customer, as well as assets that support business operations. The asset classes are Distribution Pipe, Distribution Stations, Utilization, Growth, Compression Stations, Liquefied Natural Gas, Transmission Pipe and Underground Storage, Fleet and Equipment, Real Estate and Workplace Services, and Technology and Information Services. At this time, the Asset Management Program does not consider EGI's affiliates. The Asset Management Program is a component of EGI's Integrated Management System which provides a systematic approach to managing safety and reliability across the organization.

#### Asset Management Program

Asset Management goals include employee and public safety, compliance, value to stakeholders and financial performance. EGI's value-based decision-making incorporates environmental sustainability, and the transition of customers' needs to low-carbon energy solutions. EGI employees must consider these goals when evaluating costs, risks, and performance related to asset investment decisions over the whole asset life cycle. Decisions are made through documented and transparent evaluation processes including recent additions related to the IRP Framework (EB-2020-0091).

EGI leverages an Asset Management Program based on the industry standard, Global Forum on Maintenance & Asset Management (GFMAM), to demonstrate a systematic and coordinated approach to asset management activities. Consistent practices, processes and tools are used to manage assets optimally and sustainably. This is achieved by balancing cost, risk, and performance throughout the asset's life cycle while providing value to customers and stakeholders.

#### Policy Statements

1. EGI continuously improves and aligns its asset management approach across all asset classes within EGI, by driving innovation in the development of people, tools, processes, and solutions.
2. EGI is committed to prudent value-based decision-making that incorporates energy transition for all asset-related investments on a holistic evaluation of cost, risk, and performance.
3. EGI is committed to sustainable/lower-carbon initiatives, including IRP, and new energy solutions, as well as the incorporation of these strategies within Asset Management planning and investment decisions.
4. EGI is committed to a continual, comprehensive condition assessment and risk review. EGI acknowledges that the understanding of the asset's life cycle is critical for decision-making and the safe and reliable delivery of energy.
5. EGI acknowledges that asset information is critical to transparent knowledge-based decision-making. EGI ensures that its processes, systems and controls collectively strive to deliver verifiable, traceable, complete, timely, accurate and accessible asset information.
6. EGI is committed to meeting or exceeding compliance with all applicable laws and regulations, industry codes, standards and internal policies.
7. EGI is committed to understanding and delivering value to its customers and stakeholders.
8. EGI uses this policy and EGI's Asset Management Program to guide asset investments, as endorsed by Senior

Leadership, over the life cycle of each asset class.

## 3.2 EGI Integration and Continual Improvement

This document reflects the integrated utility's Asset Management Plan for the next 10 years, with assets for the rate zones (the EGD and the Union North and South rate zones) being maintained separately for capital planning purposes in 2023 and as EGI from 2024 through to the end of 2032.

EGI continues to evolve its asset management practices to produce a comprehensive Asset Management Plan. As a result, the following changes were implemented:

- **Energy Transition**

This AMP incorporates assumptions for customer additions, peak hour demand and peak day demand, each of which have been adjusted to reflect EGI's current view of the impacts of the Energy Transition (see Exhibit 1, Tab 10, Schedule 4). EGI acknowledges that energy transition is evolving and that investment decisions will be based on the best information at the time, including consideration of IESO's forecast electricity demand. EGI maintains its obligation to serve and is committed to implementing IRP with the intent of evaluating and comparing both supply-side and demand-side options to meet an energy system need in the immediate, medium and longer term.

- **Integrated Resource Planning (IRP)**

IRP represents a significant change to the facility planning that EGI has performed in the past and, as such, EGI is taking steps to develop processes, resources and capabilities to integrate new IRP requirements into its existing asset management process and other processes. EGI's AIPM process now incorporates the IRP assessment process. The IRP assessment step of the AIPM process (see **Section 4.3.4.1**), determines if an IRPA evaluation is required for each system need, and, if so, a cost-effective IRPA exists. Further details on the IRP assessment process can be found in EGI's IRP Annual Report.

Through the IRP assessment process, EGI has performed IRP Binary Screenings on eligible projects, consistent with the guidance provided by the OEB in its Decision. The IRP Binary Screening results and the associated IRPA evaluation statuses, by project, can be found in **Appendix B – IRP**.

- **Alignment with Enbridge Inc.'s 2022 Enbridge Strategic Priorities**

Enbridge Inc. published a revised Strategic Plan in 2022. The alignment of EGI's Asset Management Policy, Asset Management Strategies and dimensions of risk have been reviewed to confirm alignment and are found in **Section 4**.

- **Organizational structure changes to align roles and responsibilities within the integrated utility**

The phase two Boundary and Real Estate initiative has been completed. EGI's regional boundaries and real estate assets across the province were reviewed to align current boundaries and strategically locate EGI's operating depots. The second phase of the initiative evaluated the area between the GTA West and Southeast regions. In January 2022, the regional borders were realigned to optimize the facilities within each new region.

- **Consolidation of asset data**

The systems of record for asset data in the Union rate zones include Maximo for meter, work, damage and condition data; SAP-PM for station work and asset data; GIS for pipe data; and CORR for corrosion data. Some data that supports the Asset Management Plan is now being migrated to a datamart as part of the integration of work and asset management systems. Ongoing documentation and consolidation of these datasets will enable EGI to analyze inventories more efficiently for the combined utility and better support the Integrity and Asset Management functions.

- **Evolution of asset condition and strategies**

**Section 5**, which addresses asset inventory, condition, risk/opportunity and strategy outcomes, has been updated to reflect the current understanding of assets. Specific project and program information is provided in **Section 6** to support each asset class's strategic plans. Key changes are:

- Review, comparison and integration where feasible of asset strategies, asset classes, asset condition, inventories, programs and processes between the two legacy companies
- Mapping the capital expenditures presented in **Section 5** to the asset class strategy
- Identification of outstanding items that remain in legacy programs until they can be integrated

- **Integration items to highlight**

Standards for installation, inspection, operation, maintenance, and asset decommissioning continue to be integrated. This work is ongoing; some legacy practices continue to be followed for each rate zone as analysis deemed it as appropriate for the assets at this time. Other design changes may be implemented on a go-forward basis. These new

standards are reflected in this Asset Management Plan and will continue to evolve throughout the integration process. Specific integration efforts include:

- **Integrity Management Program**

EGI continues to evolve its Integrity Management Program based upon industry best practices and incident learnings. EGI has developed a quantitative risk model to assess the primary risk for pipeline assets within the distribution system which is being leveraged to identify and prioritize assets that are approaching end of life and need to be replaced. Transmission pipeline assets already have a quantitative risk model; however, that model has also been enhanced with additional hazards and consequences, as well as the development of Safety Targets to further assess the risk of Transmission Integrity Management Program (TIMP) assets.

Detailed documented assessments (i.e., Integrity Plans) for assets or assets groups are being created to ensure the following:

- All potential hazards are considered.
- Appropriate inspection methods and timing are determined.
- Inspections are completed.
- Results are assessed.
- Any required repairs are made.
- The fitness for continued service is confirmed.

EGI has introduced the use of Safety Cases as an independent check that all hazards have been effectively considered and addressed. Safety Cases will initially be developed for a subset of the TIMP assets and expanded to other assets over time.

- **Fleet and Equipment**

EGI continues to standardize processes and procedures related to the assignment of vehicles for the appropriate roles, types of vehicles required to support employees in performing their roles, and vehicle maintenance and repair model.

- **Technology and Information Services**

TIS continues to support process and system integration while in parallel reducing EGI operational and cybersecurity risks. EGI continues to align systems, processes and procedures, prioritized based on business value (efficiency, safety/reliability, security, compliance) while adopting industry best practices regarding cloud computing where feasible.

- **Modelling enhancements from Distribution Optimization Engineering**

EGI has harmonized its approach to degree day forecasting and system modelling for growth; the resultant facility requirements form the basis for reinforcement forecast in this Asset Management Plan.

- **Operationalizing the Asset Plan**

As EGI develops the maturity of its Asset Management practice, greater focus is placed on measuring delivered work relative to planned work, highlighting the need for multi-year planning and the identification of resources required to execute the plan, including the resources required to scope, plan and obtain required approvals. Accomplishments of this initiative include:

- Documented and communicated Asset Investment Planning and Management (AIPM) processes, procedures, and accountabilities.
- Improved communication and training to promote consistency.
- Identification of incremental resources to support delivery of the asset investment plan.

- **10-Year Asset Management Plan**

This version of EGI's AMP considers a ten-year horizon with the understanding that the scope of investments in the earlier years of the plan are more refined than those in later years. Considering a 10-year window allows time to consider and develop feasible IRPAs to meet the identified system needs.

- **Value Assessment Quality Assurance Approach**

As the application of the Copperleaf value framework evolves, EGI has developed a continual improvement approach to validate and calibrate investment data, capture best practices, and to maximize value in the AMP. Emphasis was placed on applying data analytics practices and sense-checking investment data to better understand how EGI's value assessment processes are working and how they can be improved. Implementing this approach led to:

- Increased support for Asset Management optimization and calibration activities to ensure consistency and alignment of investment data.
  - Greater stakeholder engagement and transparency of value across EGI's portfolio of opportunities.
  - Identification and documentation of improvements to the Copperleaf value framework.
- **Greenhouse gas emission reductions**

Enbridge continues to evaluate and implement facility emission reduction opportunities by ensuring initiatives effectively balance customer preferences, compliance obligations, anticipated future regulations and other benefits such as safety and operational reliability. In the evaluation of system expansion alternatives, the cost of fuel and carbon are considered along with operational requirements. These opportunities are tracked through the GHG Scope 1 & 2 Working Group. The GHG Scope 1 & 2 Working Group will identify and review potential opportunities and strategies to achieve cost-effective GHG reductions, which are incorporated into asset class life cycle strategies, as well as operating practices, equipment modernization and innovation, and emerging policies and regulations. EGI's efforts in reducing its environmental footprint are closely tied to the work outlined in this Asset Management Plan.

## 3.3 Energy Transition

All three levels of government (federal, provincial and municipal) as well as Indigenous groups are focused on addressing climate change by reducing GHG emissions through setting targets and implementing policies. At the same time, access to energy and energy affordability are key issues that must be addressed in Ontario and EGI remains obligated as the supplier of last resort to meet the peak design day demands of its existing customers safely and reliably.

EGI is committed to partnering with the province, as well as municipalities and Indigenous groups across the province, to achieve the various GHG emission reduction targets set out within their respective energy transition and sustainability plans, including increasing energy efficiency and reliance on renewable energy sources.

This Asset Management Plan outlines the needs and resultant investments of EGI's assets to ensure that EGI can safely and reliably meet the peak design day demands of new and existing customers and how EGI is beginning to transition assets to meet future energy needs. EGI has conservatively included some assumptions related to energy transition in the forecasts EGI uses for planning purposes. This AMP incorporates assumptions for customer additions (see **Section 5.1.4**), peak hour demand and peak day demand, each of which have been adjusted to reflect EGI's current view of the impacts of the Energy Transition. For more detail, refer to Exhibit 1, Tab 10, Schedule 4.

EGI acknowledges that energy transition is evolving and that investment decisions will be based on the best information at the time. As practical, verifiable and prudent alternatives are available and energy transition assumptions are understood, EGI will adjust and adapt its planning processes to continue to securely, safely and reliably serve customers giving due consideration to the evolving nature of the use of natural gas. EGI is anticipating developments in the following areas:

- Increased adoption of low-carbon technologies
- Implementation of economically and technically feasible IRPA's
- Refinement of energy transition assumptions as information is confirmed, impacting the following:
  - EGI's forecasting methodologies for customer connections and growth
  - Adjustments to asset life cycle considerations and strategies
  - Updates in timing and scope of reinforcement investments

EGI has engaged two external consultants, (1) Posterity Group and (2) Guidehouse, to analyze the impact of climate policies and energy transition. The Guidehouse study showed that a diversified pathway, one that continues to leverage the existing gas infrastructure, is a more affordable, reliable and resilient pathway for Ontario. In a diversified pathway, the current gas system transitions over time to deliver low-carbon fuels, including hydrogen and RNG. A discussion of this work can be found in Exhibit 1, Tab 10, Schedule 5. In addition, based on the feedback EGI received in the 2024 Rate Rebasing Customer Engagement, the majority of customers agree that EGI should actively invest in low-carbon options and solutions that will help reduce environmental impacts.

EGI's Hydrogen Strategy is described in **Section 5.1.8**, which includes the expansion of EGI's existing Low Carbon Energy Project in Markham and evaluating the extent that hydrogen can be used in the distribution system and other company assets. These proposals will allow EGI to increase the amount of hydrogen the Company is delivering and inform the future state of Hydrogen as a low carbon energy source at EGI.

EGI's RNG Station Strategy is described in **Section 5.2.4.6.1.7**, where EGI is pursuing opportunities to inject this into the distribution system as RNG becomes more available.

In addition to hydrogen and RNG, EGI outlines the energy transition-related initiatives it is exploring and pursuing in Exhibit 1, Tab 10, Schedule 6.

### 3.3.1 Integrated Resource Planning (IRP)

In 2021, the OEB released its Decision and Order in the Enbridge Gas Inc., Integrated Resource Planning Proposal (EB-2020-0091) which indicated that EGI's AMP should include the status of consideration of IRP Plans in regard to meeting system needs, the result of binary screening and details on the evaluation. **Appendix B** has been included in the AMP to meet that commitment; **Sections 3.3.1** and **6.3** of this AMP provide a high-level background and context for this Appendix. The **Appendix B** tables provide the review status of each investment in the AMP that went through binary screening.

EGI has been focused on advancing IRP as directed in the OEB's IRP Decision (EB-2020-0091). At the time the Decision was issued, EGI staff were in the process of identifying system needs to support the 2023-2032 Asset Management Plan. These needs are traditionally addressed through facility alternatives which take several weeks and sometimes months to develop and evaluate, and to determine if they warrant capital investment. In parallel to this process, EGI developed an approach to screen and evaluate IRPAs in alignment with the high-level IRP process laid out by the OEB in its Decision. In the development and initial implementation of this approach, EGI has directed a significant effort towards the following activities:

- 1) **Review of Identified Investments in the 2023-2032 Capital Plan and Binary Screening:** The 2023-2032 capital plan was finalized in June 2022. Although the 2023-2032 capital plan contains investments that were also in the 2021-2025 AMP, Enbridge Gas felt it was most prudent to finalize the 2023-2032 capital plan prior to the initiation of its IRP assessments, as investment scope, cost and timing were expected to change within the first harmonized, combined, utility asset management plan. The review of projects and application of the IRP binary screening criteria was then completed for all 3087 projects within the 2023-2032 capital plan.
- 2) **IRP Pilot Project Selection:** The IRP Decision (EB-2020-0091) indicated that two IRP pilots should be selected and implemented by December of 2022. This IRP Pilot assessment and selection process was resource and time intensive, as it involved several steps and discussions, including meetings with the IRP Technical Working Group (TWG) for feedback. Efforts were focused on the following aspects.
  - a. Definition of the pilot objectives, key considerations, and criteria for selection, such as system configuration, customer mix and potential for peak hourly flow data collection.
  - b. Review of projects in the 2023-2032 capital plan and short-listing projects and associated systems as potential pilot options; factoring in the objectives and pilot section criteria.
  - c. Detailed review of potential pilot project options including the identified system needs (multiple for the portfolio pilot), system growth and peak hour demand reductions required.
  - d. High-level IRPA feasibility evaluation; this included reviewing supply-side bridging solutions and understanding the system and market characteristics to help gauge the potential of implementing a geo-targeted solution.
- 3) **Technical Evaluation:** A technical evaluation is the first step of the IRP two stage evaluation process. Investments in the 2023-2032 capital plan cover a wide range of assets, that are managed by numerous teams throughout EGI. The IRP team engaged investment owners, SMEs and Asset Managers to together determine how IRP principles would apply to their projects. The IRP team is now working with the same group of investment owners, SMEs and Asset Managers to complete a detailed review of the projects, as outlined in **Section 6.3.4 Technical Evaluation Project Review**.
- 4) **Economic Evaluation:** An economic evaluation is the second step of the IRP two stage evaluation process. This step relies on the DCF+ Test. As directed in the IRP Decision, the IRP team is engaged in enhancing the DCF+ economic evaluation test that will be utilized to determine the optimal IRP or facility solution. To date, this work has involved engaging a consultant to assess how the DCF+ test could be evolved, jurisdictional scans to better understand how other utilities have assessed non-pipeline alternative investments and whether those learnings are applicable to EGI. Additionally, an IRP TWG subgroup has been formed to discuss considerations and issues brought forward by members of the TWG for the enhanced DCF+ test.
- 5) **IRP TWG Meetings** were previously held monthly, now biweekly. The IRP team has dedicated time and resources to prepare materials for these meetings. Various teams are engaged to contribute content, as well as, addressing the takeaway items from the previous meeting.

**Appendix B** reflects the current state of EGI's IRP Assessment process, as described in **Section 4.3.4.1** of the AMP. **Section 6.3** provides details on the methodologies and process, and the **Appendix B** tables that follow provide the evaluation at the investment level, at the time of filing. EGI will continue to assess investments in the 10-year capital plan for IRPA feasibility. As this is the first year that EGI has applied the IRP Framework to the AMP, a detailed and time-intensive review of all facility-based investments has been required, which includes an in-depth evaluation of the projects to understand the project need, drivers, system grouping opportunities and potential for IRP alternatives. The IRP Assessment Process will become less time intensive as it is further integrated into the Solution Planning & Value Assessment stage of the AIPM process, and as it becomes focused on new investments or those that have changed since the last iteration of the AMP.

## 3.4 Structure and Scope of EGI's Asset Management Plan

**Figure 3.4-1** is an illustration of EGI's Asset Management Plan structure.

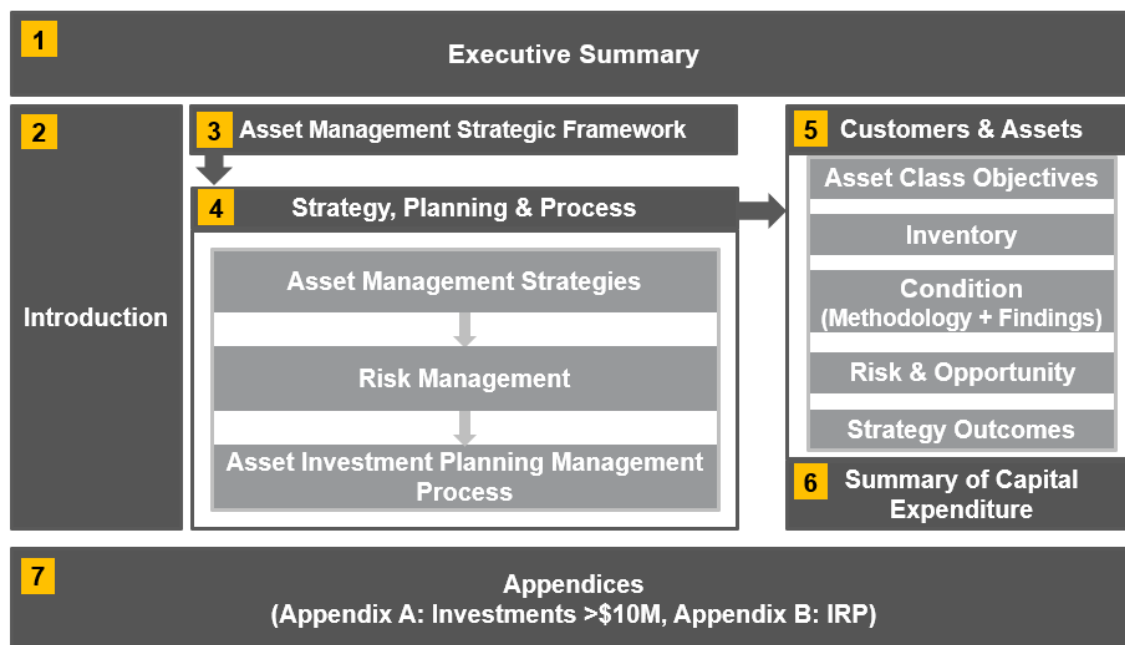

Figure 3.4-1: EGI's Asset Management Plan Structure

**Executive Summary (Section 1):** This section provides a summary of the Asset Management Plan.

**Introduction (Section 2) and Asset Management Strategic Framework (Section 3):** This plan starts with an introduction to EGI. It also highlights EGI's stakeholder commitment, the asset management framework and policy, updates and improvements from previous Asset Management Plans, Energy Transition, IRP, and the structure of the document.

**Strategy, Planning and Process (Section 4):** This section details the alignment of asset management at EGI with the Enbridge strategic priorities and includes EGI's asset management strategies, risk management and the Asset Investment Planning and Management (AIPM) process.

**Customers and Assets (Section 5):** This section details the following:

- EGI's customers and the customer growth projections
- Asset class objectives
- Asset class strategies
- Asset inventory
- Asset condition
- Risks and opportunities
- Strategy outcomes
- Capital investments to meet life cycle strategies

**Summary of Capital Expenditure (Section 6):** This section summarizes the 10-year capital investment plan for EGI by rate zone, outlines the optimization process and highlights key assumptions used for **Sections 5 and 6**. Note that projects where solution scopes are still under development are not currently included in EGI's 10-year portfolio of spend.

**Appendices (Section 7):** The appendices present supporting information for the Asset Management Plan. Appendix A includes descriptions of discrete investments with a Net Base Capex greater than \$10M in 2023 to 2032. Appendix B – IRP contains the IRP Binary Screening and associated IRPA evaluation statuses by project.

## 4 Strategy, Planning and Process

EGI's Asset Management framework is aligned to Enbridge's Strategic Priorities, the EGI Asset Management Policy and Asset Management Strategies (see **Section 4.1**). This alignment provides a foundation that supports the Asset Investment Planning and Management (AIPM) process (see **Section 4.3**).

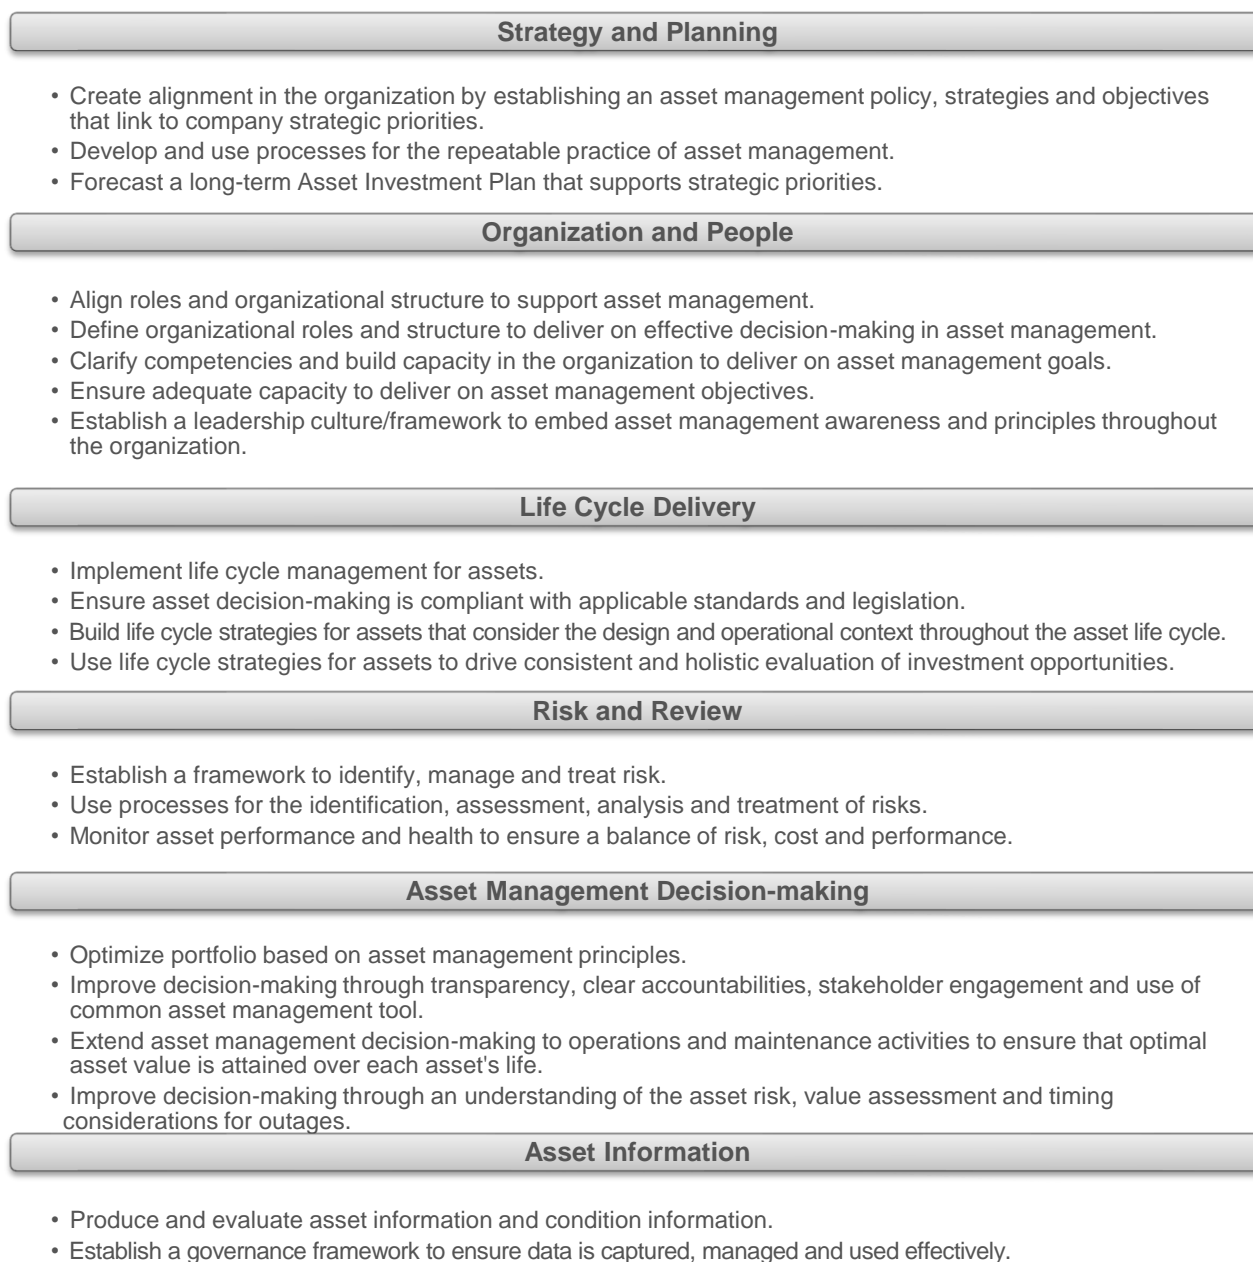

Figure 4.0-1: Asset Management Alignment

- **Enbridge Strategic Priorities (Section 2.2.2)** sets the foundation for all company-wide operations and initiatives.
- **Asset Management Policy (Section 3.1.2)** translates the Enbridge Strategic Priorities into the application of asset management at EGI and outlines the high-level goals and principles used to manage assets.
- **Asset Management Strategies (Section 4.1)** supports the policy and outlines the methods employed for asset management success.
- **Risk Management Process (Section 4.2)** involves a series of activities designed to help management assess, prioritize, and treat hazards and risks that could affect the achievement of key business objectives.
- **Asset Investment Planning and Management (AIPM) Process (Section 4.3)** outlines how the identified strategies will be executed.

## 4.1 Asset Management Strategies

The EGI Asset Management Program's day-to-day activities are driven by key asset management strategies (see **Figure 4.1-1**) aligned to the six framework components of the IAM Conceptual Asset Management Model (see **Figure 3.1-1**) and operationalized through the Asset Investment Planning and Management (AIPM) process (see **Section 4.3**):

**Figure 4.1-1: Asset Management Strategies**

## 4.1.1 Strategy and Planning

EGI uses a governance framework to align asset management plans and decision-making within the Enbridge's overall strategic objectives. The strategies to achieve this are:

- Create alignment in the organization by establishing an asset management policy, strategies and objectives aligned to strategic priorities.
- Develop and use processes for the repeatable practice of asset management.
- Forecast a long-term Asset Investment Plan that supports strategic priorities.

The alignment of EGI's Asset Management Program with organizational priorities (see **Figure 4.1-2**) and a well-defined asset portfolio enables the development of asset-specific programs and investments. The Asset Management Plan is a coordinated activity combining these components to forecast a long-term (10-year) plan for asset investments at each rate zone. Forecasting long-term asset investment plans allows EGI to identify future needs for asset investments and make proactive decisions.

The capital investment summary for EGI's Asset Management Plan can be found in the Summary of Capital Expenditure (see **Section 6**).

4.1.1.1 Alignment of Enbridge Strategic Priorities and Asset Management Strategies

Figure 4.1-2 illustrates how EGI's Asset Management Policy, strategies and value measures align with Enbridge's strategic priorities. This alignment is the core of EGI's Asset Management Strategic Framework.

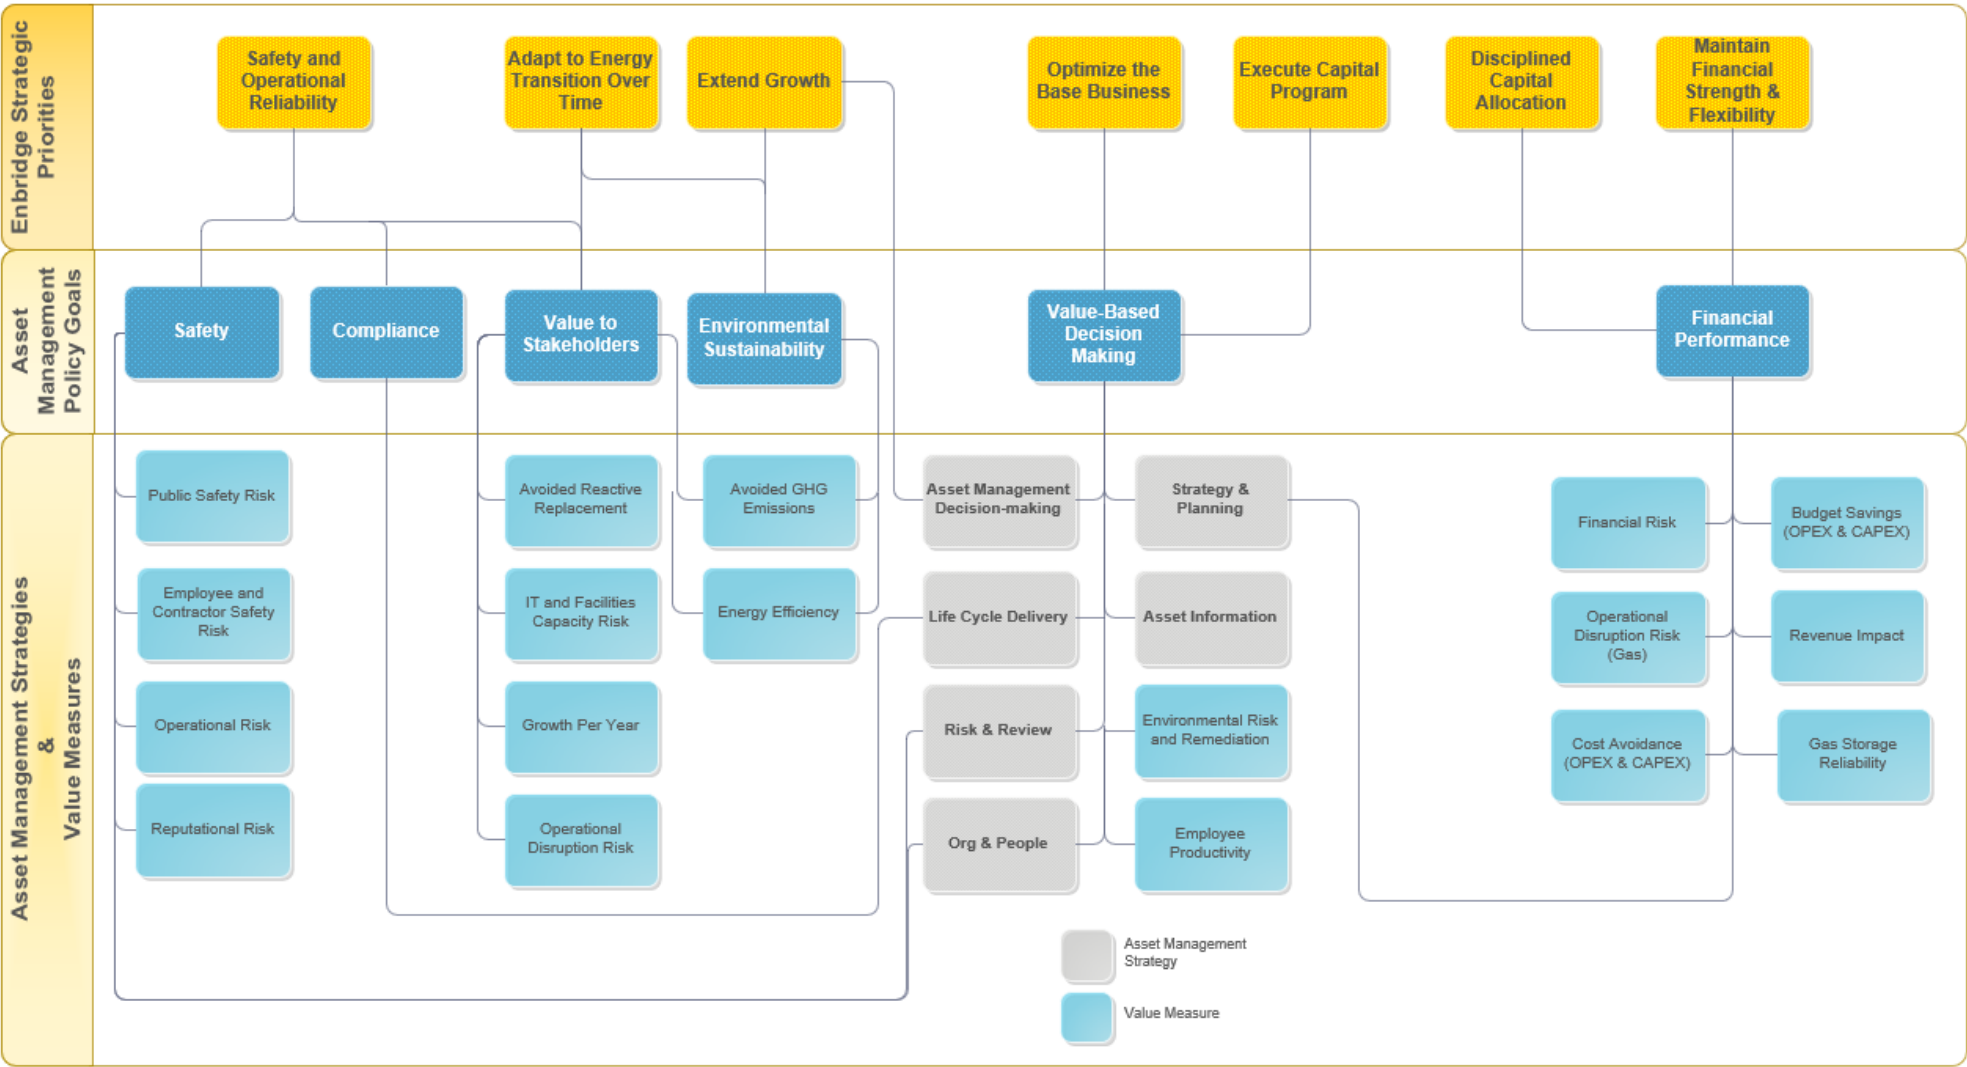

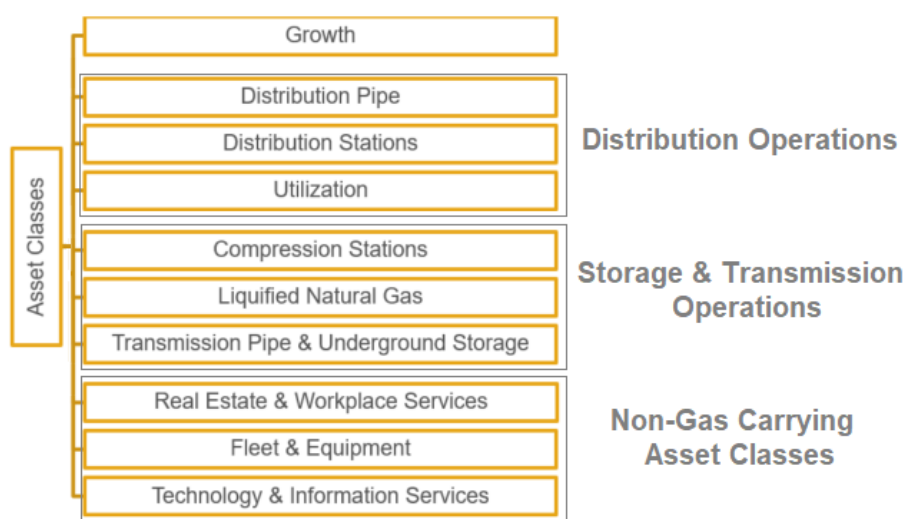

Figure 4.1-2: EGI's Alignment of Enbridge Strategic Priorities and Asset Management Strategies

## 4.1.2 Organization and People

EGI aims to develop and maintain an adequate supply of competent and motivated people, in key asset management roles across all levels, to support the organization in delivering asset management objectives. The strategies to achieve this are:

- Align roles and organizational structure to support asset management.
- Define roles and structure for the organization to deliver on effective decision-making and asset management.
- Clarify competencies and build capacity in the organization to deliver on asset management goals and objectives.
- Establish a leadership/culture framework to embed asset management awareness and principles throughout the organization.

Asset classes at EGI (see **Figure 4.1-3**) are used to categorize and manage investment decisions. Each asset class has its own asset manager, who is responsible for understanding the operational risks and opportunities for their asset class and for managing the portfolio of work to ensure risk is managed to the lowest practicable level and optimum value is realized.

**Figure 4.1-3: EGI Asset Classes**

A matrix approach to asset management (see **Figure 4.1-4**) enables the coordinated activity of defining an optimized and approved portfolio of work. This streamlines inputs from a diverse group of business stakeholders, while growing asset management practices across EGI.

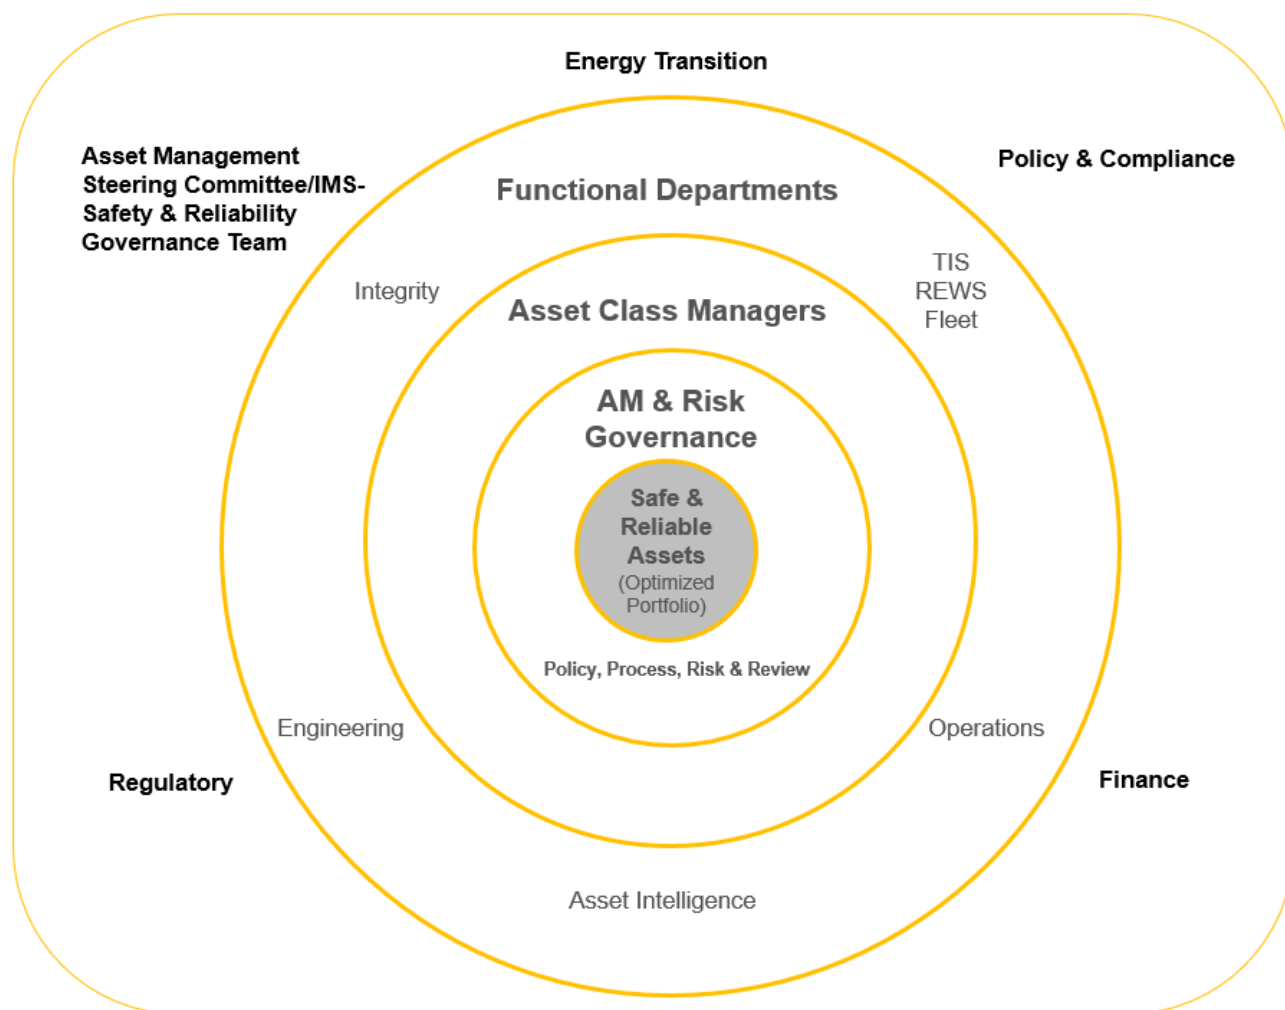

Asset management is embedded throughout all levels of the organization. Overall guidance is established through the Asset Management Steering Committee, the Integrated Management System (IMS) and the Safety and Reliability Governance Team. Key functions in this matrix approach work together to achieve an optimized portfolio:

- The **Asset Management Director** performs the following:
  - Demonstrates commitment to values and principles of Asset Management set out in the Asset Management Policy, Objectives and Strategic Asset Management Plan
  - Promotes continual improvement
  - Decides on the set of investments that will address risk across EGI through the recommendation of the capital portfolio
  - Ensures resources for the Asset Management Plan are available and actively directs and supports people to contribute to effective asset management
  - Supports and influences staff to deliver the Asset Management Strategy and objectives of the organization
  - Endorses Asset Management Plan documentation
- **Asset Management and Risk Governance** establishes and governs the following:
  - Asset Management Policy
  - Leadership culture to embed Asset Management principles (through organizational change management and training)

- Asset management systems
- Risk Management Framework, Standards, Processes and Value Framework
- Asset Investment Planning & Management processes and tools
- Portfolio optimization
- Preparation and approval of the Asset Management Plan
- **Asset Managers** perform the following:
  - Understanding of asset condition and failure drivers
  - Consolidation of emerging and existing risks, opportunities, and emerging needs
  - Preparation of investments for value assessment
  - Proposal of potential solutions to identified needs
  - Prioritization of solutions and risk treatments across the asset class
  - Development of strategic plans for the asset class which incorporates IRP
  - Stakeholder review and management
- **Functional/Process Departments** support asset management by providing:
  - Integrated Resource Planning Alternative assessments
  - Engineering assessments
  - Value assessments
  - Integrity assessments
  - Energy transition design and analysis
  - Risk owner, accountable for ensuring that a risk is managed throughout the Risk Management Lifecycle (see **Section 4.2**)
  - Asset analytics
  - Records management
  - Financial support
  - Regulatory support including energy policy
  - Tacit knowledge (including identification of existing and emerging issues)
  - Planning and design
  - Safety and incident information
  - System analysis long-range planning
  - Project execution

Together, these roles provide the structured support for the Asset Investment Planning and Management process described in **Section 4.3** to ensure that capital expenditures are based on transparent and defensible asset-based decisions.

**Figure 4.1-4: A Matrix Approach to Asset Management**

### 4.1.3 Life Cycle Delivery

EGI aims to have clear ownership, accountabilities, policies and processes to manage all physical assets throughout their entire life cycle. The strategies to achieve this are:

- Implement life cycle management for assets.
- Ensure asset decision-making is compliant with applicable standards, legislation and regulatory decisions.
- Build life cycle strategies for assets that consider the design and operational context throughout the asset life cycle.
- Use life cycle strategies for assets to drive consistent and holistic evaluation of investment opportunities.

Life cycle strategies for assets drive the consistent and holistic evaluation of needs and opportunities. With clear objectives for the use and operation of assets, life cycle costs can be examined to ensure that optimal asset value is attained over the asset's life.

EGI has defined asset life-cycle stages that are applied to all asset classes (see **Figure 4.1-5**), adapted from the IAM Conceptual Asset Management Model (see **Figure 3.1-1**):

- Design/Construct
- Operate
- Maintain
- Renew/Retire

Using these life-cycle stages, strategies are developed for each asset class to support asset investment decisions. **Table 4.1-1** describes the typical activities for each life cycle stage.

**Figure 4.1-5 Asset Life Cycle Stages**

**Table 4.1-1: Life-Cycle Management for Assets**

| Life-Cycle Stage        | Activities   |
|-------------------------|--|
| <b>Design/Construct</b> | <ul style="list-style-type: none"> <li>• Design new assets to:</li> <li>• Ensure the safe and reliable delivery of natural gas.</li> <li>• Ensure worker and public safety.</li> <li>• Ensure code compliance.</li> <li>• Support energy transition.</li> <li>• Meet current and future demand requirements.</li> <li>• Reduce risk to the lowest practicable level.</li> <li>• Ensure critical components and systems have multiple layers of failure protection.</li> <li>• Ensure components and systems can be made safe in a reasonable period.</li> <li>• Minimize environmental impact and GHG emissions.</li> <li>• Minimize future maintenance needs.</li> <li>• Suit business purpose and ensure safe business function.</li> <li>• Procure materials to meet or exceed applicable codes, standards and policies.</li> <li>• Construct/install assets to meet or exceed codes, standards, designs and procedures for safe and reliable operations.</li> <li>• Create asset records to meet or exceed standards, policies and procedures that are traceable, verifiable, complete and correct.</li> </ul> |
| <b>Operate</b>          | <ul style="list-style-type: none"> <li>• Operate the system to:</li> <li>• Ensure the safe and reliable delivery of natural gas.</li> <li>• Ensure worker and public safety.</li> <li>• Meet or exceed compliance standards and procedures.</li> <li>• Meet current demand.</li> <li>• Minimize end-user disruption.</li> </ul>  |

| Life-Cycle Stage    | Activities   |
|---------------------|--|
|                     | <ul style="list-style-type: none"> <li>• Use assets in the most cost-effective manner.</li> <li>• Extend asset life.</li> <li>• Suitably commission assets for safe, efficient and reliable use by employees and contractors.</li> <li>• Provide business and employees with support and service for optimal use of company assets and business solutions.</li> <li>• Monitor the performance and use of assets to inform future life cycle decisions.</li> </ul>  |
| <b>Maintain</b>     | <ul style="list-style-type: none"> <li>• Maintain integrity of gas-carrying assets to minimize loss of containment, extend asset life and ensure compliance with codes, standards and procedures.</li> <li>• Maintain gas-carrying assets and safety controls to avoid overpressure or delivery outages.</li> <li>• Maintain asset information to meet or exceed standards set out by EGI.</li> <li>• Determine probability and consequence of failure to inform maintenance and repair programs.</li> <li>• Maintain competency levels to ensure work is performed by qualified and competent workers.</li> <li>• Continue to improve methods to maintain and extend life of assets, ensuring a balance between risk, cost and performance.</li> </ul>  |
| <b>Renew/Retire</b> | <ul style="list-style-type: none"> <li>• Determine probability and consequence of failure to inform renewal decisions.</li> <li>• Develop proactive renewal programs for assets that are nearing end-of-life (informed by data and tacit knowledge and tracked in the Integrated Management System).</li> <li>• Renew or replace assets to meet the changing needs of the business, support employee and contractor health and safety, support energy transition, meet or exceed regulatory and compliance requirements, increase efficiencies and reduce overall GHG emissions.</li> <li>• Renew or replace assets to meet the changing needs of the business, increase performance, realize efficiencies and address obsolescence.</li> <li>• Retire assets using a process that meets or exceeds regulatory codes and standards.</li> </ul> |

## 4.1.4 Risk and Review

EGI aims to manage risks through the adoption of a Risk Management process (see **Section 4.2**) based on ISO 31000 and the Enbridge Framework Standard on Risk Management. The strategies to achieve this are to:

- Establish a framework to identify, analyze, evaluate, and treat risk.
- Implement processes based on the framework to management risks.
- Monitor asset performance, health and risk to balance risk, cost and performance.

Asset performance, health and risk is monitored through a range of formal and informal methods including condition assessment programs, tracking of performance data through Management Programs (part of the Integrated Management System), the Asset Health Review and the Hazard Identification and Risk Assessment process.

Through these inputs and the Risk Management process, EGI manage risks in the following categories:

- **Employee and Contractor Health and Safety:** Level of injury or illness and number of employees impacted
- **Public Health and Safety:** Level of injury or illness and number of people in general public impacted
- **Environmental:** Breadth and severity resulting in environmental damage/impact
- **Financial:** Level of financial impact
- **Operational:** Length of time and breadth of impact on utility and transportation customers and diversion of resources
- **Reputational:** Level of media coverage, impact on customers, potential penalties or impact on ability to operate due to compliance issues

## 4.1.5 Asset Management Decision-Making

EGI aims to have a clear framework for asset investment decision-making that balances risk, cost and performance throughout the asset life cycle. The strategies to achieve this are:

- Optimize portfolio based on asset management principles.
- Improve decision-making through transparency, clear accountabilities, stakeholder engagement and use of a common tool.
- Extend asset management decision-making to further include operations and maintenance activities to ensure that optimal asset value is attained over each asset's life.
- Improve decision-making through an understanding of the asset context and timing considerations for outages.

Investments fall into one of three categories based on asset management principles: mandatory, compliance or value-driven, as described in **Table 4.1-2**. These categories support portfolio optimization and the determination of optimal investment timing through the AIPM process **Section 4.3**.

**Table 4.1-2: Investment Categories**

| Investment Category | EGI Description   |
|---------------------|---|
| <b>Mandatory</b>    | An investment that is required to address a risk or opportunity within its required time window. Mandatory investments can be the result of: <ul style="list-style-type: none"> <li>• Exceeding an established risk upper threshold</li> <li>• Third-party relocation</li> <li>• Program work with sufficient history and risk to warrant continuation</li> <li>• Projects that meet the economic feasibility tests in <i>EBO 188</i> and <i>EBO 134</i></li> </ul> |
| <b>Compliance</b>   | Investments required to adhere with applicable laws and regulations, industry codes, standards and internal policies. Compliance investments receive the same treatment as mandatory investments—both must be addressed within their required time frame.   |
| <b>Value-Driven</b> | Investments whose timing is determined based on consideration of the value it brings to the ratepayer and the organization. Value and investment timing can be informed via the <b>Copperleaf value framework</b> or via the GDS Risk Management process (see <b>Section 4.2</b> ).   |

EGI uses Copperleaf, an asset investment planning tool that provides a common economic scale, to understand and evaluate proposed capital investments. Copperleaf allows EGI to optimize its investment portfolio based on the defined capital considerations (see **Section 6.1.2**), use a normalized scale to support value-based decision-making, and helps to ensure EGI fulfils its regulatory and internal requirements for systematic and transparent investment decisions.

Copperleaf supports the AIPM process (see **Section 4.3**) by:

- Allowing the documentation of risk management opportunities and treatment options
- Capturing growth opportunities
- Providing context on value-driven investments through the value framework, to demonstrate alignment with the Asset Management Policy and organizational strategic priorities
- Performing portfolio optimizations using iterative scenarios to determine an optimal spend profile
- Allowing investment details to be updated throughout the year to optimally manage the investment portfolio
- Providing full transparency to business stakeholders on the approved work plan and understanding year-over-year changes

For value-driven investments (see **Table 4.1-2**), an organization needs a mechanism to determine its investments' relative value. Several elements can contribute to the overall value of an investment, such as:

- The type and severity of the risks treated by an investment
- Financial impacts such as cost savings
- Overall cost of the investment
- Impacts to Key Performance Indicators (KPIs)
- Service measures
- Overall organizational value additions

An investment's value is quantified through Copperleaf's value framework or evaluated via the GDS Risk Management process. The investment timing and scope of work for investments that rely on the GDS Risk Management process is typically

more complex—investment timing is confirmed outside of Copperleaf optimization. For value-driven investments that use the Copperleaf value framework, value measures are used to quantify an investment's value, as described in **Table 4.1-3**.

Value measures are investment attributes that are evaluated objectively based on risk or opportunity to determine how the investment delivers value to Enbridge and the ratepayer. These value measures are placed on an economic scale to assist in optimization. An investment's net value is used to determine both its independent merit and its standing among other investments in a constrained optimization process.

The **Copperleaf value framework** is an analytical framework that complements risk assessments, allows for comparison of dissimilar investments and enables portfolio optimization. Each of the Enbridge's strategic priorities (see **Section 2.2.2**) is comprised of one or more value measures. For more details on valuing investment risk, see **Section 4.2.3**.

**Table 4.1-3: EGI's Value Measures**

| Value Measure   | Description  |
|---|--|
| <b>Employee and Contractor Health and Safety Risk</b> | Measures the risk of employee and contractor safety incidents that will be mitigated through the completion of an investment.  |
| <b>Public Health and Safety Risk</b>                  | Measures the risk of public safety incidents treated through the completion of an investment.  |
| <b>IT and Facilities Capacity Risk</b>                | Measures the risk that the organization would not be capable of continued service at acceptable levels following a disruptive incident.  |
| <b>Operational Risk</b>                               | Measures the mitigation of the risk of disruptive incidents preventing Enbridge from operating or serving its customers.   |
| <b>Reputational Risk</b>                              | Measures the treatment of the risk of incidents that would be perceived poorly by customers, the media and stakeholders through the completion of an investment.   |
| <b>Gas Storage Reliability</b>                        | Measures the financial benefits of investments that increase the reliability of gas storage assets to prevent supply interruptions.  |
| <b>Environmental Risk and Remediation</b>             | Measures the treatment of risk of environmental incidents through the completion of an investment.   |
| <b>Operational Disruption Risk (Gas)</b>              | Measures the societal cost of a disruption in the distribution of gas to customers.  |
| <b>Growth Per Year</b>                                | Measures the expected customer growth per year the system serves.  |
| <b>Avoided GHG Emissions</b>                          | Measures the monetary value of reducing CO <sub>2</sub> greenhouse gas emissions through the completion of an investment.  |
| <b>Avoided Reactive Replacement</b>                   | The financial savings of replacing an asset proactively before it fails and not having to pay the higher, reactive replacement costs.  |
| <b>Financial Risk</b>                                 | Measures the treatment of potential financial risks, such as financial losses due to damage of equipment/company assets, if the investment is not completed.   |
| <b>Revenue Impact</b>                                 | Measures the impacts to the total amount of gross income generated by Enbridge's primary operations. Revenue represents the total income earned before expenses are deducted.  |
| <b>Budget Savings OPEX</b>                            | Values the OPEX Budget Savings of the investment.  |
| <b>Budget Savings CAPEX</b>                           | Budget savings is the net benefit between the anticipated cost increases to the CAPEX budget as well as cost savings to current planned spending. This is not the Investment Cost.   |
| <b>Cost Avoidance OPEX</b>                            | Any action that avoids having to incur OPEX costs in the future (these costs would be unbudgeted/unplanned). Cost avoidance measures are never reflected in financial statements or the annual budget. Avoided OPEX costs are only reflected in instances where a proposed action is not implemented, thus resulting in a cost increase.   |
| <b>Cost Avoidance CAPEX</b>                           | Any action that avoids having to incur CAPEX costs in the future (these costs would be unbudgeted/unplanned). Cost avoidance measures are never reflected in financial statements or the annual budget. Avoided CAPEX costs are only reflected in instances where a proposed action is not implemented, thus resulting in a cost increase. |

| Value Measure         | Description  |
|-----------------------|--|
| Energy Efficiency     | Measures the financial benefits through annual energy savings and reduced CO <sub>2</sub> emissions. |
| Employee Productivity | Measures the impact on working conditions and employee productivity.                                 |

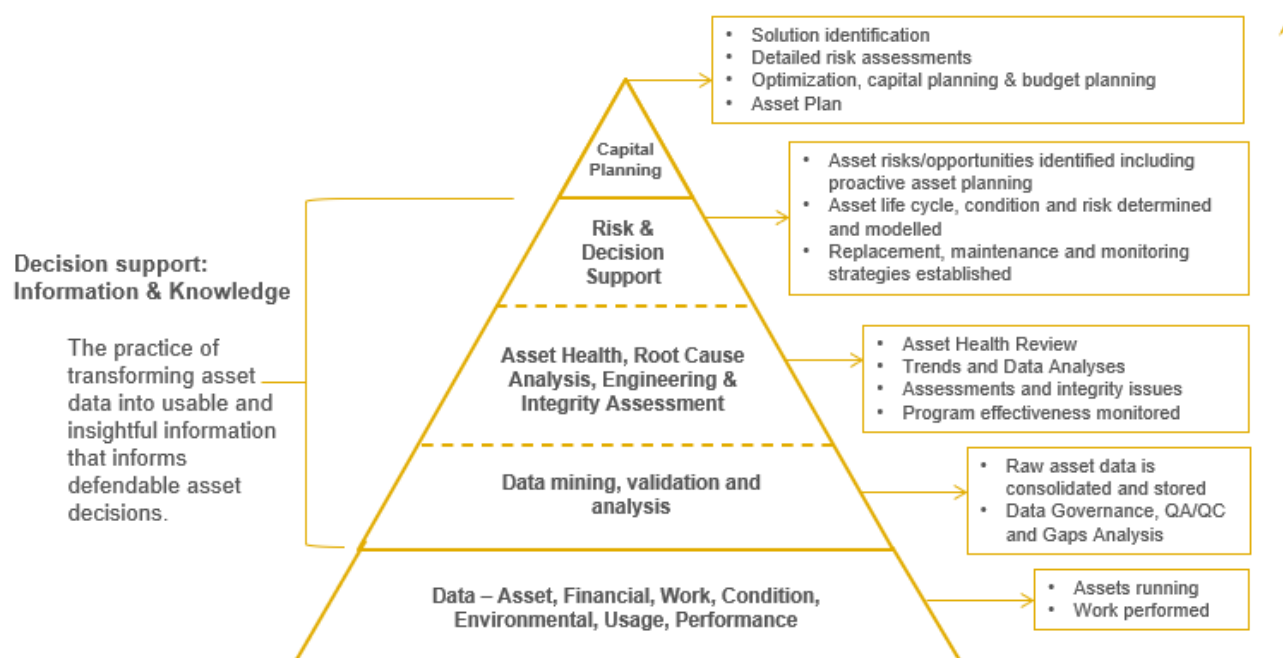

EGI has been implementing and continues to mature its asset management decision-making practice.

## 4.1.6 Asset Information

EGI aims to have the right systems, processes and data to support asset management. This is foundational to all other asset management capabilities. The strategies to achieve this are:

- Produce and evaluate asset information and condition information.
- Establish a governance framework to ensure data is captured, managed and used effectively in decision-making.

Asset data provides the foundation for asset investment planning (see **Figure 4.1-6**). Asset analytics supports people, processes and technology advancements to enable defensible asset decisions. Asset analytics provides asset information that informs and supports asset health reviews, engineering reliability assessments, risk and opportunity assessments and asset replacement strategies. It also outlines the processes, governance and systems required to ensure decisions are defensible and repeatable through using data that is fit for purpose.

**Figure 4.1-6: Asset Information and Support to Asset Investment Planning**

Asset data enables the evaluation of existing assets, determines patterns, supports costing of solution options and identifies meaningful information to inform life cycle management strategies. Several reports and tools are used to inform asset investment planning. Supported by EGI and industry knowledge, asset information is leveraged for asset analytics and modelling to:

- Assess asset condition
- Support and predict risk and value assessments
- Develop cost estimates and understand financial performance
- Inform and support asset health reviews and engineering reliability assessments

- Establish asset inventory and population over time
- Ensure compliance with EGI policy and regulatory requirements
- Make operational asset decisions, e.g., emergency response
- Ensure safe and reliable operations e.g., core work, maintenance

## 4.2 Risk Management

A risk is defined as the negative impact of uncertainty on the organization's objectives expressed as the combination of the likelihood and consequence of a potential event. To manage risk, the Risk Management process, which is consistent with *ISO 31000* (see **Figure 4.2-1**), involves a series of activities designed to help the organization assess, prioritize and treat risks.

**Figure 4.2-1: Enbridge Risk Management Process**

The following sections provide more detail about the process steps and the roles involved in Risk Management at EGI.

### 4.2.1 Identify Risk

Operational hazard and risk identification occur throughout the asset life cycle and are identified through:

- Internal sources such as databases, frontline processes, targeted reviews, assessments and meetings
- External sources such as published industrial incidents, industry-related publications distributed by regulatory bodies and industry associations, local governments, external crime statistics, industry standards and accepted best practices.

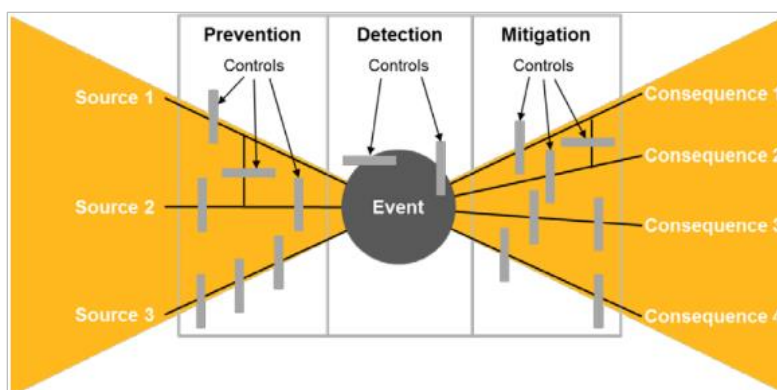

### 4.2.2 Analyze Risk

Risk factors shown in the Risk Bowtie Model (see **Figure 4.2-2**) are analyzed and assessed. The commonly used types of risk assessments at EGI are quantitative, semi-quantitative and qualitative which are described in **Table 4.2-1**. The selection of the approach is dependent on the scope of the assessment, maturity of risk assessment technique, best available data and information at the time of the assessment and the types of assets.

**Table 4.2-1: Risk Assessment Types**

| Type                              | Description  | Application  |
|-----------------------------------|--|--|
| <b>Qualitative Approach</b>       | General and/or structured brainstorming with a multidisciplinary team to identify and evaluate risks. Relies mainly on qualitative inputs such as expert judgment, experience and technical knowledge. | Used to identify and understand risk factors.  |
| <b>Quantitative Approach</b>      | Detailed technical assessments that leverage numerical data and mathematical methods to quantify risks.  | Applied to contexts which are well understood and where numerical data and mathematical models can be used to quantify risk factors. |
| <b>Semi-Quantitative Approach</b> | Relies on qualitative inputs, such as expert judgment, experience and technical knowledge, as well as numerical data and mathematical methods to evaluate risk.  | Applied to contexts which are relatively well understood but not all risk factors can be quantified.                                 |

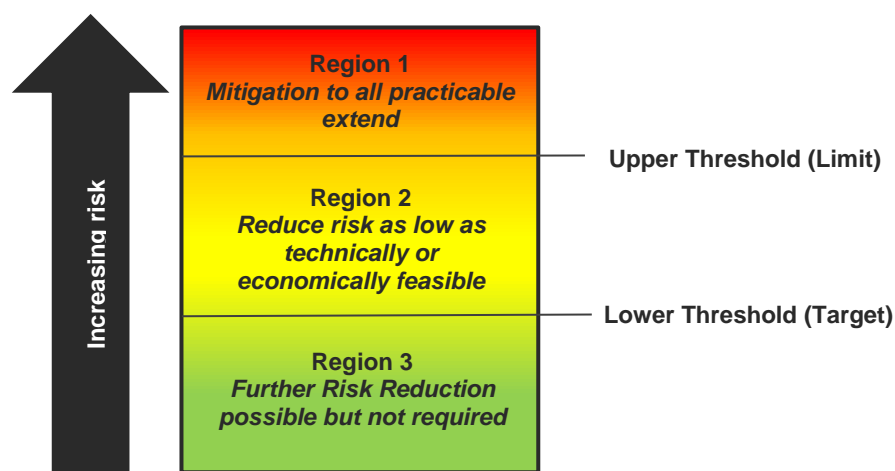

Source: Adapted from IEC/ISO 31010 (2009)

**Figure 4.2-2: Risk Bowtie Model**

In order to provide clear guidance on prioritizing resources on managing risks, the EGI Risk Evaluation Framework (see **Figure 4.2-3**) is applied. When a risk is assessed to be in Region 1, risk treatment must be taken to reduce risk to all practicable extent. The timing of risk treatments to reduce risk may vary by scenario with reduction occurring as soon as possible while following applicable standard operating procedures and related business processes and requirements. Risk in Region 2 must be treated unless it can demonstrate that the risk has already been reduced as low as technically and economically feasible. Region 2 acknowledges that there are practical limits to ability to reduce risk. Risks in Region 3 do not require further treatment but, like risks in other Regions must be monitored according to applicable procedures and related businesses' processes and requirements.

The framework ensures that resource allocations are prioritized to EGI's higher risks to ensure safe and reliable operations. It also ensures the ability to demonstrate that all reasonable measures have been undertaken to reduce risk.

**Figure 4.2-3: EGI Risk Evaluation Framework**

As EGI evolves its risk management practices, two approaches have been adopted from industry best practices; Enbridge Risk Matrix (see **Figure 4.2-4** where the Y-axis indicates likelihood, and the X-axis indicates consequence) and risk thresholds (upper and lower thresholds) as illustrated in **Figure 4.2-3**.

**Figure 4.2-4: Enbridge Risk Matrix**

In most cases, the risk matrix is used to support comparison of risks across multiple dimensions where risks are estimated in terms of likelihood and consequence with results being plotted on the matrix. The EGI Risk Evaluation Framework (see **Figure 4.2-3**) and the Enbridge Risk Matrix (see **Figure 4.2-4**) are complementary and support risk informed decision-making.

Sometimes there is a need to understand safety risks due to release of hazardous materials such as flammable and toxic material and their intersection with the public and employees, also known as catastrophic/rare events. In such cases, risk quantification can be applied, provided there are data and analytical techniques to allow for this.

The safety risk evaluation criteria proposed by the Risk Management Task Force (RMTF) (formed by the CSA under the Technical Committee for Z662 Standard on the Oil and Gas Pipeline System) are used for this type of assessment, the criteria have also been adopted by UK Health and Safety Executive (UK HSE). This approach is also in use at major North American energy companies<sup>3</sup>. These criteria are represented by lower and upper thresholds (i.e., target and limit) as shown in the EGI Risk Evaluation Framework (see **Figure 4.2-3**).

While the EGI Risk Evaluation Framework can support treatment prioritization and risk reduction, ultimately, the actions EGI takes in the face of specific risks are influenced by many factors including the business environment, regulatory, planning, financial, commercial, stakeholders and the quality and maturity of risk assessment data and capabilities. The risk assessment and decision to treat a risk are inputs to the Asset Investment Planning and Management process (see **Section 4.3**).

## 4.2.3 Evaluate Risk

Having analyzed the risk, the EGI Risk Evaluation Framework (see **Figure 4.2-3**) is used to provide guidance on prioritizing resources on managing risks. For more details on Risk and Review, see **Section 4.1.4**. Once decisions are made to treat risks, they are documented with treatment plans as part of the Risk Management process. Depending on the nature of the risk, these risks may be reported quarterly through EGI's Integrated Management System processes.

The level of uncertainty of a risk evaluation needs to be considered and can influence the confidence in likelihoods and consequences of specific scenarios. Where level of uncertainty is higher it may be necessary to further augment quantitative assessments with qualitative considerations.

<sup>3</sup> Tomic, Aleksandar, Kariyawasam, Shahani, "Critical Review of Risk Criteria for Natural Gas Pipelines", Proceeding of the 2016 11<sup>th</sup> International Pipeline Conference IPC 2016-64356, Calgary, AB, September 26-30, 2016.

## 4.2.4 Treat Risk

Risk treatment is the modification of identified risks, ranging from day-to-day operational activities undertaken by operators and field personnel to inspect equipment, to a large capital project required to replace an existing asset. Operating inspections, procedures and preventive maintenance activities are developed during the commissioning of an asset and are used to treat identified risks throughout the Operate and Maintain phases of the asset life cycle.

**Figure 4.2-5** lists the risk treatment options used at EGI. The maintenance strategy for a facility or asset is established based on operating standards requirements, the outputs of a reliability centered maintenance study or Original Equipment Manufacturer (OEM) recommendations. These risk treatment options are considered during the Solution Planning and Value Assessment stage (see **Section 4.3.2**) of the AIPM process.

**Figure 4.2-5: Spectrum of Risk Treatment Options**

## 4.2.5 Monitor and Review Risk

EGI maintains a risk register to communicate and review all operational risks. Risks are reported and reviewed on a quarterly basis through a risk reporting process. Each management program owner within the Integrated Management System and each risk owner is also accountable for the ongoing management of risks within their accountabilities.

## 4.3 Asset Investment Planning and Management (AIPM) Process

Within the overall Asset Management Strategic Framework, as capital investment needs are identified, they are evaluated and executed through the Asset Investment Planning and Management (AIPM) process (see **Figure 4.3-1**). **Figure 4.3-1** represents the current state AIPM process that was used to develop the 2023-2032 Capital Portfolio and Appendix B - IRP, the future state AIPM process will incorporate the IRP Assessment process at the Solution Planning & Value Assessment stage.

Figure 4.3-1: EGI AIPM Process

### 4.3.1 Identify Investment Need

Capital investment needs enter the AIPM process via EGI's asset investment planning tool (Copperleaf). An investment need is either a risk or opportunity to the organization. The investment need can be entered directly into Copperleaf, or it may arise through the Risk Management process (see **Section 4.2**) once an identified risk is determined to require capital treatment. The following investments are entered directly into Copperleaf:

- Growth and cost-saving opportunities
- Compliance investments
- Ongoing programmatic spend with sufficient history and risk to warrant continuation

Once an investment need is captured in Copperleaf, the asset manager validates that the need aligns with the strategies for the asset class and that a capital investment is required. Once confirmed that a capital investment is indeed required, solution planning and value assessment (if applicable) can begin.

Depending on the required timing to address the identified investment need with a solution, an investment may be considered for portfolio optimization or may be considered emergent, where it is approved off-cycle from budgeting activities; emergent investments require capital within the current year and are reviewed case-by-case by the asset manager and Asset Management Governance.

### 4.3.2 Solution Planning and Value Assessment

Solution planning is initiated once an investment need is approved by the asset manager and can occur in parallel with the completion of a value assessment (when required). A Copperleaf investment contains a scope, cost estimate and preferred timing for all identified solutions (facility and non-facility) to address the need. Investments can be in the form of a **Project** or a **Program**, as described in **Table 4.3-1**.

Table 4.3-1: Project and Program Descriptions

| Investment Type | EGI Description   |
|-----------------|---|
| <b>Project</b>  | A one-time individual initiative with a distinct scope and timeline.  |
| <b>Program</b>  | An overarching initiative to address a risk/opportunity that is/will be comprised of multiple projects with varying scopes and timelines. |

Cost estimating is an important activity for the solution planning process and the resultant Asset Management Plan. Cost estimates include the direct capital costs, retirement costs and rebillable credits. In addition, any avoided and/or additional operating and maintenance costs are estimated where known and captured in the value assessment. All estimates are based

on current year costs (except for programs that have a defined scope). Note that scoping and estimating for earlier years of the plan will be more accurate than later years.

All solution options have a cost estimate, and the level of accuracy is established using estimate classes (see **Table 4.3-2**). The class of the estimate also informs the level of contingency applied to the project or program.

Contingency is described as the amount of funds budgeted to account for unquantified project costs at the time the estimate is completed; this cost is intended to cover potential risks during execution. Contingency is generally included in estimates with the expectation for it to be expended and allocated on a project-by-project basis based on asset class, project risk and scope of work.

**Table 4.3-2: Estimate Classes**

| Class          | Estimate Description                                | Scope Maturity  | Contingency Level |
|----------------|---|-----------------|-------------------|
| <b>Class 5</b> | High-level cost estimate                            | Very Low        | High              |
| <b>Class 4</b> | Estimate based on initial information               | Low             | ↓                 |
| <b>Class 3</b> | Estimate based on cost-estimating tools and reports | Moderate – High | ↓                 |
| <b>Class 2</b> | Estimate based on Request for Proposal (RFP)        | High            | ↓                 |
| <b>Class 1</b> | Estimate based on quote or project completion       | Very High       | Low               |

All value-driven investments have their value assessed in Copperleaf once a scope and cost estimate have been defined. Where there is more than one option to address a risk or opportunity, each option is value assessed. The value assessment quantifies the amount of risk reduced and any value gained by the proposed solution option based on the value measures defined in **Table 4.1-3**. The combination of value measures and investment cost is referred to as the total investment value, which is used to prioritize investments in optimization. While the value measures will differ between investments and solution options, the total investment value allows comparison of dissimilar investments.

### 4.3.3 Optimize Portfolio of Solutions

With solution planning and value assessment complete, portfolio optimization is performed in Copperleaf, where a multi-year investment plan is created based on asset management principles. Prior to optimization, proposed investments are reviewed with business stakeholders to ensure all known risks and opportunities to the organization are captured. The portfolio is then optimized to determine the optimal investment timing for investments that have flexible timing, with constraints on the annual net direct capital and consideration of available resources.

A 10-year time frame is analyzed to determine the long-term capital forecast. Based on required timing, projects and programs have varying degrees of detail; work details proposed earlier in the plan are more refined than work details proposed towards the outer half of the 10-year span. For this reason, programmatic spend is proposed to address risks, where projects are continually defined and attached to programs as scope refinement occurs.

Once all investments are categorized based on **Table 4.1-2**, portfolio optimization begins. Investments identified as mandatory, compliance, or value-driven using the Risk Management process are automatically slotted at the required time rather than using risk and cost to determine optimal timing. Value-driven investments using the Copperleaf value framework are free to shift within the optimization time frame.

Prior to optimizing, an initial portfolio representing the preferred option and timing of investments is captured. This typically results in an inconsistent spend profile over the 10 years, with a much larger proposed spend in earlier years.

Optimization scenarios are determined through the consideration of the following:

- Approved or proposed budget
- Historical capital spends at the organization
- Risks that must be treated because they exceed a threshold in EGI Risk Management process (see **Section 4.2**)
- Asset life cycle strategies
- The original proposal of work (preoptimization) and an understanding of the associated compliance and mandatory projects/programs

Using Copperleaf, the EGI portfolio is optimized and analyzed by varying the net direct capital per year, highlighting the effects of project timing, option selection and value. The results from these scenarios are reviewed with asset managers to find the combination of investment options and start dates that best meet business needs within specified constraints. This scenario is

then reviewed and refined to deliver a final portfolio recommendation. Iterative adjustments are applied, and the recommended portfolio is approved once validated against timing and resourcing constraints.

### 4.3.4 Produce Capital Portfolio

The capital portfolio is captured in Microsoft Excel as well as Copperleaf. This provides business stakeholders with broad access to the approved capital plan and encourages working on a multi-year plan. The use of Copperleaf enables ongoing refinement of investments in the plan and periodic review of changes and updates to understand their impact.

#### 4.3.4.1 IRP Assessment Process

Once the capital portfolio is produced, EGI uses an IRP assessment process, which includes a binary screen and an IRPA evaluation, to determine the best approach to meet identified system needs/constraints. In a project-specific application (Leave to Construct or IRP Plan), EGI demonstrates that it has followed this process including the results of the analysis at each of the following stages:

1. Identification of Constraints
2. Binary Screening Criteria
3. Two-Stage Evaluation Process
4. Periodic Review

EGI is beginning to integrate the IRP assessment process into its annual planning activities. With 2022 being the first year that EGI has implemented the IRP assessment process, the projects are evaluated after the Produce Approved Capital Portfolio (see **Section 4.3.4**) step in the AIPM process. Once EGI has completed the review of projects in this Asset Management Plan, the process will be adjusted to occur as part of Solution Planning and Value Assessment (see **Section 4.3.2**). It is anticipated that over the next couple of years the IRP assessment process is expected to occur during both Stages 2 and 4 of the AIPM process, in order to ensure all projects have been assessed and reevaluated as required. The result of EGI's IRP Assessment Process is summarized in **Section 6.3**.

### 4.3.5 Execute Annual Portfolio Plan

During project planning and execution, periodic forecasts track project and program costs, and reports are generated on actual incurred costs.

EGI acknowledges that the identification of risks and the execution of projects is dynamic. During the year, project scopes may change or new projects may arise, resulting in cost pressures (increases or decreases) to the current portfolio. As these pressures are identified, trade-off decisions are made based on value and available capital, a direct demonstration of EGI's Plan-Do-Check-Act cycle (see **Figure 3.0-2**).

All requests for emerging or revised investments are supported with clear purpose, need and timing to allow for evaluation. An overall review is conducted to understand various uncertainties and to ensure that as much risk and opportunity is addressed as possible within the constraints of the portfolio. The execution of the annual work plan is monitored and adjusted monthly through the forecasting process and informs the performance of EGI's Asset Management Program.

### 4.3.6 AIPM Performance Review

Performance measurement provides insight into assets, asset management performance and the effectiveness of the asset management system. To determine AIPM performance, four key areas are evaluated:

- The end-to-end asset management process
- Delivery to plan of the approved portfolio (Scope Delivery to Plan and Capital Budget Delivery to Plan)
- Adherence to asset class objectives (see **Section 5**)
- Accomplishment of specific asset management objectives

**Scope Delivery to Plan** is the comparison of the approved portfolio project list to actual projects completed at the end of the fiscal year. Variances are explained to ensure the Asset Management Framework is supporting the reduction of risk and realizing optimal asset value.

**Capital Budget Delivery to Plan** is informed monthly by the capital forecast. This ensures the governance and controls are in place to optimize the capital plan while operating within an approved budget. It also supports continuous improvement for cost estimating, where the variance between estimate and actual costs are understood and learnings are incorporated in future planning.

**Asset Class Objectives** have been defined for all asset classes at EGI. These objectives, aligned with asset management goals and principles, outline asset requirements to support successful business operations. Life cycle management is applied across all asset classes to specify strategies that govern decision-making throughout the four stages of the asset life cycle: Design/Construct, Operate, Maintain and Renew/Retire. Adherence to the asset class objectives and life cycle strategies ensures consistent and holistic evaluation of risks and opportunities, setting the foundation for successful asset planning and value realization. Asset class objectives are found in Customers and Assets (see **Section 5**).

The **Asset Management Health Check** will detail specific asset management execution elements supporting the overarching asset management strategies. As asset management is a management program within EGI's Integrated Management System, the management program health check will inform senior management of the effectiveness of the Asset Management team in maturing the Asset Management Program.

## 5 Customers and Assets

This section provides details on the following:

- EGI's customers and the customer growth projections
- Asset class objectives, risks and opportunities
- Asset inventory and condition
- Asset class strategic plans to meet life-cycle strategies

In **Figure 4.3-1**, it can be seen that natural gas delivers a significant portion of Ontario's energy needs on both a peak and average basis. EGI provides this energy safely, affordably and reliably, and is committed to delivering this energy with net-zero operational emissions by 2050. EGI also contributes positively to the low-carbon economy through its investments in innovative low-carbon solutions such as hydrogen and renewable natural gas. In addition, when compared with electricity, natural gas continues to be cost-effective, delivers approximately two times the energy and over four times the peak demand, through underground infrastructure that is less susceptible to the weather events that impact electrical infrastructure, offering much needed resiliency.

**Figure 4.3-1: The Energy Landscape in Ontario**

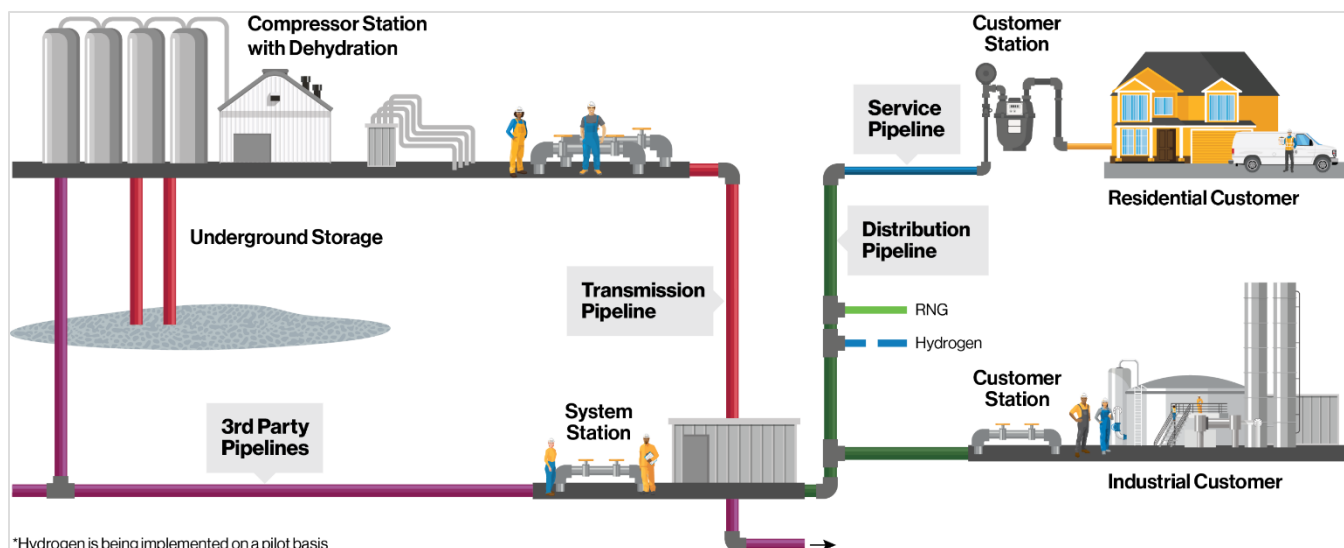

EGI also provides natural gas storage and transportation services for other utilities and energy market participants in Ontario, Quebec and the United States. EGI's storage and transmission system forms an important link in the movement of natural gas from Western Canadian and U.S. supply basins to Central Canadian and Northeast U.S. markets.

Storage and transmission assets include transmission pipe of up to nominal pipe size (NPS) 48 used to transport natural gas across Ontario, compressor plants to move natural gas to and from storage reservoirs and along the transmission pipelines, and a liquefied natural gas plant used to support peak shaving in one area of the company.

EGI's distribution assets include smaller diameter pipe, stations, meters and regulators at homes in the franchise areas. EGI's supporting assets include buildings, fleet vehicles and technology and information services assets across Ontario that support EGI's critical business needs and activities.

EGI has a network of assets that serve to receive, store, transport and distribute energy. **Figure 4.3-2** shows how these assets and those that support them are interconnected to provide safe and reliable natural gas to EGI's customers.

**Figure 4.3-2: Components of a Natural Gas System and Supporting Assets**

## 5.1 Growth

EGI delivers safe and reliable natural gas to over 3.8 million customers, and this customer base is forecast to grow over the 10-year period of this Asset Management Plan. EGI services residential, apartment, commercial, industrial and transmission customers within its franchise areas. As practical, verifiable and prudent alternatives are available, the Growth asset class will continue to evolve to incorporate low-carbon technologies and implement energy transition and IRPAs.

The Growth asset class consists of assets to serve the addition of new customers based on new housing or business starts, customers converting to natural gas from another fuel source, as well as equipment and service upgrades to accommodate existing customer load growth. EGI continues to connect customers with natural gas service within its franchise area, consistent with the requirements of *EBO 188* while also considering Integrated Resource Planning alternatives (IRPAs). The Growth asset class is divided into five subclasses:

- **Customer Connections** activity evaluates customers' natural gas consumption needs and ensures demands are assessed and processed in accordance with the guidelines prescribed in the *EBO 188* report. The assets and costs within this asset subclass include materials and installations of distribution mains, services, meters and regulating equipment.
- **Distribution System Reinforcement** projects involve the installation or modification of existing gas distribution assets to maintain minimum required system pressures, maintain distribution capacity and meet growing natural gas demands. These projects are primarily driven by increased customer demand, customer growth and system reliability considerations. The IRP Assessment Process is used to evaluate the preferred solution to meet the specific system needs (see **Appendix B – IRP**).
- **Community Expansion** projects involve the installation of gas distribution assets to serve communities that have not previously had access to natural gas and that are not feasible without funding support. These projects are driven by municipal and/or community interest and supported by an Ontario Energy Board (OEB)-approved funding mechanism of a System Expansion Surcharge (SES) from all connected customers as well as government-approved ratepayer-supported funding under *Bill 32: Access to Natural Gas Act, 2018*.
- **Transmission System Reinforcement** projects involve the installation or modification of existing gas transmission assets to maintain minimum required system pressures, maintain distribution capacity and meet growing natural gas demands in accordance with the *EBO 134* report. These projects are driven by increasing in-franchise and ex-franchise demand growth. Capital costs related to transmission system reinforcements are included in the expenditure summary for the Transmission Pipe and Underground Storage asset class (see **Section 5.3.6.4**). The IRP Assessment Process is used to evaluate the preferred solution to meet the specific system needs (see **Appendix B – IRP**).
- **Hydrogen Blending** projects look for ways in which EGI can reduce GHG emissions through the introduction of hydrogen into the natural gas distribution system and other company assets. With the Q4 2021 in-service date of the Markham Hydrogen Blending Pilot Project (approximately 2% of the gas stream by volume), EGI operates the first North American hydrogen blending facility. Engineering has monitoring standards in place to ensure safe and reliable operations. As hydrogen blending matures and evolves, strategies for maintenance and replacement of existing infrastructure will be established. As government regulations are set and enacted, EGI will continue to respond with programs and projects to meet these requirements with its various existing assets in addition to new assets.

The Growth capital expenditure requirements for materials and asset installation is based on forecast customer growth over the next 2023-2032. To account for the evolving energy transition, reinforcement projects are screened and analyzed in accordance with the IRP Framework (EB-2020-0091 [Appendix A]) and best available energy transition related information. Capital expenditure requirements related to the condition of existing assets (mains, services, measurement, and regulating equipment, etc.) are addressed in the **Distribution Operations** and **Storage and Transmission Operations** asset classes.

## 5.1.1 Growth Objectives

The Growth asset class is a key component of the Design/Construct stage of EGI's Asset Management Life Cycle. It supports EGI's investment in new assets related to customer growth. Growth objectives are listed in **Table 5.1.1-1**.

**Table 5.1.1-1: Growth Asset Class Objectives**

| Asset Class Objectives                  | Description   |
|---|---|
| <b>Integrated Resource Planning</b>     | Screen projects using EGI's IRP assessment process; for those that pass, determine if there are IRPAs that are economically and technically feasible.   |
| <b>System Growth</b>                    | Ensure an engaged and positive customer experience.   |
|   | Ensure EGI provides new or upgraded natural gas services to residential, apartment, commercial, industrial and transmission customers when projects do not pass IRP Binary Screening or where IRPAs are not feasible.                       |
|   | Reinforce distribution networks and transmission systems to economically serve short- and long-term demand requirements where projects do not pass IRP Binary Screening or where IRPAs are not feasible.                                    |
